

### NC-Cap/PSR (Primary Side Regulation) CV/CC Power Switch

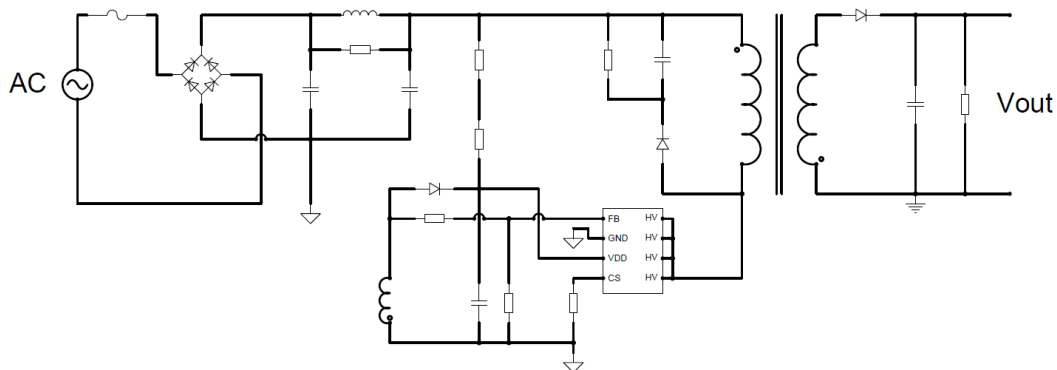

#### Features

- ▲ Low Cost Solution Built-in 800V power BJT
- ▲ Quasi-Resonant Primary Side Regulation (QR-PSR) Control with High Efficiency
- ▲ Multi-Mode PSR Control
- ▲ Fast Dynamic Response
- ▲ Built-in Dynamic Base Drive
- ▲ Audio Noise Free Operation
- ▲  $\pm 5\%$  CC and CV Regulation
- ▲ Low Standby Power <70mW
- ▲ Programmable Cable Drop Compensation (CDC) in CV Mode
- ▲ Built-in AC Line & Load CC Compensation
- ▲ Built-in Protections:
  - Short Load Protection (SLP)
  - Cycle-by-Cycle Current Limiting
  - Leading Edge Blanking (LEB)
  - Pin Floating Protection
  - VDD OVP & UVLP & Clamp
- ▲ Available with ZS304X Versions in SOP-8 Package

#### Applications

- Battery Chargers for cellular phones, cordless phone, PDA, digital cameras, etc.
- Replaces linear transformer and RCC SMPS
- Small power adapter
- AC/DC LED lighting

#### Typical Application Information

#### General Description

ZS304X is a high performance Quasi Resonant (QR) Primary Side Regulation (PSR) PWM power switch with high precision CV/CC control ideal for charger applications.

In CV mode, ZS304X adopts Multi Mode QR Control which uses the hybrid of AM (Amplitude Modulation) mode and (Frequency Modulation) FM mode to improve system efficiency and reliability. In CC mode, the IC uses PFM control with line and load CC compensation. The IC can achieve fast dynamic response. The built-in Cable Drop Compensation (CDC) function can provide excellent CV performance.

ZS304X integrates functions and protections of Under Voltage Lockout (UVLO), VDD over Voltage Protection (VDD OVP), Cycle-by-cycle Current Limiting (OCP), Short Load Protection (SLP), VDD Clamping, etc.

### NC-Cap/PSR (Primary Side Regulation) CV/CC Power Switch

## General Information

### Pin Configuration

### Absolute Maximum Ratings

Parameter	Value
HV PIN Maximum Voltage	800V
HV PIN DC Current	800mA
VDD DC Supply Voltage	30V
VDD DC Clamp Current	10mA
CS, BASE Voltage Range	-0.3 to 7V
FB Voltage Range	-0.7 to 7V
R <sub>θ</sub> JA(°C/W) (SOP-8)	90°C/W
Maximum Junction Temperature	150°C
Operating Temperature Range	-40 to 85°C
Storage Temperature Range	-65 to 150°C
Lead Temperature (Soldering, 10Sec.)	260°C
ESD Capability, HBM	±2KV
ESD Capability, MM	±400V

### Recommended Operating Conditions

Parameter	Value	Unit
Supply Voltage, VDD	7 to 24	V
Operating ambient temperature	-40 to 80	°C
Maximum Switching Frequency@ Full Loading	70	KHz
Minimum Switching Frequency@ Full Loading	35	KHz

**NC-Cap/PSR (Primary Side Regulation) CV/CC Power Switch****Pin Description**

Pin No.	Name	I/O	Function
1	FB	I	System feedback pin which regulates both the output voltage in CV Mode and output current in CC mode based on the flyback voltage of The auxiliary winding
2	GND	P	The Ground of the IC
3	VCC	P	Power Supply Pin of the Chip
4	CS	I	Current Sense input Pin
5, 6, 7, 8	HV	O	The Power BJT Collector

### NC-Cap/PSR (Primary Side Regulation) CV/CC Power Switch

#### Operation Description

ZS304X is a high performance, multi-mode, highly integrated Quasi Resonant Primary Side Regulation (QR-PSR) power switch. The built-in high precision CV/CC control with high level protection features makes it suitable for offline small power converter applications.

#### System Start-Up Operation

Before the IC starts to work, it consumes only startup current (typically 3uA) which allows a large value startup resistor to be used to minimize the power loss and the current flowing through the startup resistor charges the VDD hold-up capacitor from the high voltage DC bus. When VDD reaches UVLO turn-on voltage of 17.5V (typical), ZS303X begins switching and the IC operation current is increased to be 0.8mA (typical). The hold-up capacitor continues to supply VDD before the auxiliary winding of the transformer takes the control of VDD voltage.

Fig.1

Once ZS304X enters very low frequency FM (Frequency Modulation) mode, the operating current is reduced to be 500uA typically, which helps to reduce the standby power loss.

#### Quasi Resonant PSR CV Modulation (QR-CVM)

In Primary Side Regulation (PSR) control, the output voltage is sensed on the auxiliary winding during the transfer of transformer energy to the secondary. Fig.2 illustrates the timing waveform of

CV sampling signal, demagnetization signal (DEM) and quasi-resonant (QR) trigger signal in ZS304X.

When the CV sampling process is over, the internal sample/hold (S&H) circuit captures the error signal and amplifies it through the internal Error Amplifier (EA). The output of EA is sent to the Quasi Resonant PSR CV Modulator (QR-CVM) for CV regulation. A valley is selected to trigger new PWM cycle by the output of the QR-CVM block, which is determined by the load. The internal reference voltage for EA is trimmed to 2V with high accuracy.

Fig.2

During the CV sampling process, an internal variable current source is flowing to FB pin for Cable Drop Compensation (CDC). Thus, there is a step at FB pin in the transformer demagnetization process, as shown in Fig.2. Fig.2 also illustrates the equation for “demagnetization plateau”, where  $V_o$  and  $V_f$  is the output voltage and diode forward voltage;  $R_1$  and  $R_2$  is the resistor divider connected from the auxiliary winding to FB Pin,  $N_s$  and  $N_a$  are secondary winding and auxiliary winding respectively.

When heavy load condition, the Mode Selector (as shown in “Block Diagram”) based on EA

NC-Cap/PSR (Primary Side Regulation) CV/CC Power Switch

output will switch to CC Mode automatically.

PSR Constant Current Modulation (PSR-CCM)

Timing information at the FB pin and current information at the CS pin allow accurate regulation of the secondary average current. The control law dictates that as power is increased in CV regulation and approaching CC regulation the primary peak current is at  $I_{PP} (max)$ , as shown in Fig.3.

Fig.3

Referring to Fig.3 above, the primary peak current, transformer turns ratio, secondary demagnetization time ( $T_{dem}$ ), and switching period ( $T_{sw}$ ) determines the secondary average output current  $I_{out}$ . Ignoring leakage inductance effects, the equation for average output current is shown in Fig.3. When the average output current  $I_{out}$  reaches the regulation reference in the Primary Side Constant Current Modulator (PSR-CCM) block, the IC operates in pulse frequency modulation (PFM) mode to control the output current at any output voltage at or below the voltage regulation target as long as the auxiliary winding can keep VDD above the UVLO turn-off threshold.

In ZS304X, the ratio between  $T_{dem}$  and  $T_{sw}$  in CC

mode is 1/2. Therefore, the average output current can be expressed as:

$$I_{CC\_OUT} (mA) \cong \frac{1}{2} \times N \times \frac{500mV}{R_{cs}(\Omega)}$$

In the equation above,

N- The turn ratio of primary side winding to secondary side winding.

Rcs-The sensing resistor connected between the power BJT emitter to GND.

Multi Mode Control in CV Mode

To meet the tight requirement of averaged system efficiency and no load power consumption, a hybrid of frequency modulation (FM) and amplitude modulation (AM) is adopted in ZS304X which is shown in the Fig 4.

Around the full load, the system operates in FM mode. When normal to light load conditions, the IC operates in FM+AM mode to achieve excellent regulation and high efficiency. When the system is near zero loading, the IC operates in FM again for standby power reduction. In this way, the no-load consumption can be less than 70mW.

Fig.4

Programmable Cable Drop Compensation (CDC) in CV Mode

In smart phone charger application, the battery is always connected to the adapter with a cable wire which can cause several percentages of voltage drop on the actual battery voltage. In ZS304X, an offset voltage is generated at FB pin by an internal

current

source (modulated by CDC block, as shown in Fig.5) flowing into the resistor divider. The current is proportional to the switching period, thus, it is inversely proportional to the output power  $P_{out}$ . Therefore, the drop due the cable loss can be compensated. As the load decreases from full loading to zero loading, the offset voltage at FB pin will increase. By adjusting the resistance of R1 and R2 (as shown in Fig.), the cable loss compensation can be programmed. The percentage of maximum compensation is given by

$$\frac{\Delta V(cable)}{V_{out}} \cong \frac{I_{cable\_max} \times (R1 \parallel R2)}{V_{FB\_REF}} \times 100\%$$

For example,  $R1=3K\Omega$ ,  $R2=18K\Omega$ , The percentage of maximum compensation is given by:

$$\frac{\Delta V(cable)}{V_{out}} \cong \frac{10\mu A \times (5K \parallel 30K)}{2V} \times 100\% \cong 2.5\%$$

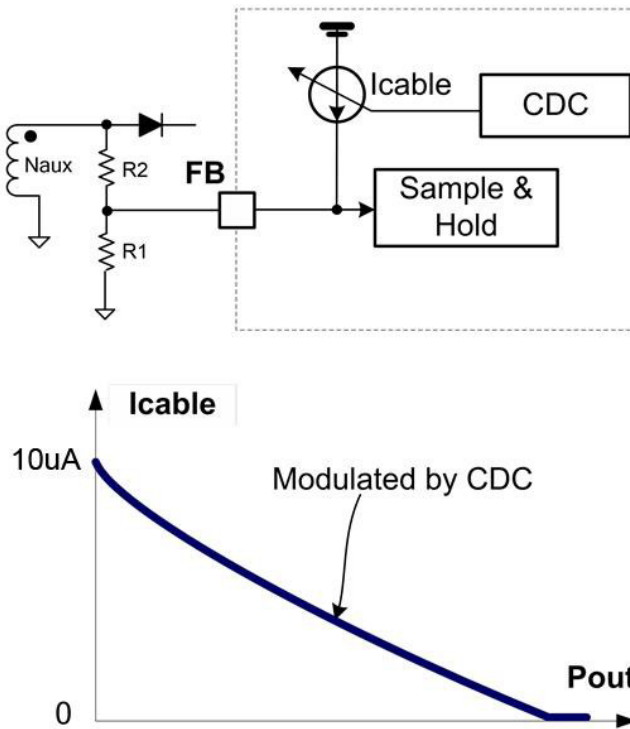

Fig.5

**Optimized Dynamic Response**

In ZS304X, the dynamic response performance is optimized to meet USB charge requirements.

**Audio Noise Free Operation**

As mentioned above, the multi-mode CV control with a hybrid of FM and AM provides frequency modulation. An internal current source flowing to CS pin realizes CS peak voltage modulation. In ZS304X, the optimized combination of frequency modulation and CS peak voltage modulation algorithm can provide audio noise free operation from full loading to zero loading.

**Dynamic BJT Base Drive**

ZS304X drive a power BJT with dynamic base drive control to optimize efficiency. The BJT base drive current ranges from 12mA to 35mA (typical), and is dynamically controlled according to the power supply load change. The higher the output power, the higher the based current. Specifically, the base current is related to CS peak voltage, as shown in Fig.6

Fig.6

**Short Load Protection (SLP)**

In ZS304X, the output is sampled on FB pin and then compared with a threshold of UVP (0.65V typically) after an internal blanking time (10ms typical).

In ZS304X, when sensed FB voltage is below 0.6V, the IC will enter into Short Load Protection (SLP)

**NC-Cap/PSR (Primary Side Regulation) CV/CC Power Switch**

mode, in which the IC will enter into auto recovery protection mode.

30V (typical) zener clamp is integrated to prevent the IC from damage.

**VDD Over Voltage Protection (OVP) and Zener Clamp**

When VDD voltage is higher than 27.0V (typical), the IC will stop switching. This will cause VDD fall down to be lower than VDD\_OFF (typical 7.0V) and then the system will restart up again. An internal
