

Sinusoidal Sensorless Three-Phase Brushless DC Motor Controller and Predriver

LV8961HUW

Overview

The LV8961 is a high performance sinusoidal sensorless three-phase BLDC motor controller with predrivers for automotive applications. An integrated two-stage charge pump provides gate current for a wide range of ultra low $R_{ds(on)}$ NFETs. The device offers a rich set of system protection and diagnostic functions such as overcurrent, overvoltage, short-circuit, undervoltage, overtemperature and many more. It supports open-loop as well as closed-loop speed control based on Back ElectroMotive Force (BEMF) observation. The user configurable startup, speed setting and proportional/integral (PI) control coefficients, make LV8961 suitable for a wide range of motor- and load combinations. With a built-in linear regulator for powering an external circuit and a watchdog timer, the LV8961 offers a very small system solution. A one-time programmable (OTP) non-volatile memory in addition to RAM and an SPI interface is provided for parameter setting and monitoring of the system status. With the operating junction temperature tolerance up to 175°C, the LV8961 is an ideal solution for stand-alone automotive and industrial BLDC motor control systems.

Features

- AEC-Q100 Qualified and PPAP Capable
- Operating Junction Temperature up to 175°C
- Operating Voltage Range from 5.5 V to 28 V with Tolerance from 4.5 V to 40 V
- Embedded Proprietary Sensorless Trapezoidal and Sinusoidal Commutation
- Selectable Number of BEMF Zero-crossing Detection Window from 6, 3, 2, and 1 per Electrical Cycle
- Simple and Effective Lead Angle Adjustment Setting by Register
- Supports Open-loop as well as Closed-loop Speed Control
- Integrated Predrivers for Driving Six N-MOSFETs
- Two-stage Charge Pump for Continuous 100% Duty Cycle Operation
- 5 V / 3.3 V Regulator and Watchdog Timer Applications Using an External Microcontroller
- Configurable Speed Settings with Linear Characteristic
- PI Control Include Acceleration/Deceleration Adjustment
- Direct Access to PWM Duty and FG Cycle via SPI Interface
- Various System Protection Features Including:
 - ◆ Shoot through Protection Using Configurable Dead Time
 - ◆ Drain-source Short Detection

ORDERING INFORMATION

Device	Package	Shipping†
LV8961HUWR2G	SQFP48K (Pb-Free)	2,500 / Tape & Reel

†For information on tape and reel specifications, including part orientation and tape sizes, please refer to our Tape and Reel Packaging Specification Brochure, [BRD8011/D](http://www.onsemi.com/BRD8011/D).

- ◆ Cycle-by-cycle Current Limit and Overcurrent Shutdown (Threshold Value can be Selectable by Register)
- ◆ Overvoltage and Undervoltage Shutdown
- ◆ Overtemperature Warning and Shutdown
- ◆ Input PWM Fault Detection
- ◆ Abnormal FG Cycle Monitoring
- ◆ Motor Pin Open Detection

Typical Applications

- Pumps (Fuel, Oil, Coolant, Hydraulic Controls, Vacuum, Solar Boilers, ...)
- Fans and Blowers (HVAC, Radiator, Condenser, Battery, Inverter, Charger, ...)
- White Goods and Industrial BLDC Motor Control

PIN ASSIGNMENTS

Figure 4. LV8961H Pinout

PIN DESCRIPTION

Pin Name	Pin No	TYPE	Description	Page
V3RO	1	TYPE 2	3 V regulator output pin. Connect capacitor between this pin and AGND	19
V3RI	2	TYPE 1	3 V regulator input pin (internally connected to control, and logic circuits). Connect to V3RO pin	19
NC	3, 14, 16, 20, 22, 24		No Connections	
DIAG	4	TYPE 4	Programmable open drain diagnostic output	21
VCC	5	TYPE 2	5 V or 3.3 V regulator output pin. (Selected by internal register setting) Power supply for microcontroller. Connect capacitor to AGND for stability	19
RXD	6	TYPE 4	Open drain logic level output of HVPIN received data. Use pull-up to a voltage less than or equal to VS	21
AGND	7		Analog GND pin	
CSB	8	TYPE 5	Active low SPI interface chip selection pin	26
SCLK	9	TYPE 3	SPI interface clock input pin	26
SI	10	TYPE 3	Active high SPI interface serial data input pin	26
SO	11	TYPE 4	Open drain SPI interface serial data output pin	26
FG	12	TYPE 4	Open drain BEMF transition output pin. The frequency division ratio is selectable via register settings	21
IGND	13	TYPE 12	HV PWMIN Block GND pin. Must be connected to AGND on the PCB	
HVPIN	15	TYPE 12	High voltage PWM input with a $V_{VS}/2$ threshold	21
LPIN	17	TYPE 3	Digital level PWM input pin for direct drive or speed register selection details. Input polarity can be programmed for either active high or active low	21
TH	18	TYPE 1	Thermistor input pin for power stage temperature detection. If the input voltage is below the threshold voltage, an error is triggered. The error threshold is programmable. To disable tie to V3RO	23
RFSENS	19	TYPE 13	Shunt resistance reference pin. Connect this pin to the GND side of the Shunt resistor with Kelvin leads	22
RF	21	TYPE 13	Output current detect pin. Connect this pin to higher terminal of the shunt resistor with Kelvin leads	22
COM	23	TYPE 9	COM input pin. Connect this pin to the motor neutral point if available. This point may be derived from a resistive network with 1 k resistors to the phases	15
SWL SVL SUL	25 29 33	TYPE 8 TYPE 8 TYPE 8	Current return path for low-side predriver. Short-circuit shutoff level is measured between this pin and its corresponding phase pin	21
WL VL UL	26 30 34	TYPE 8 TYPE 8 TYPE 8	Predriver output pin for the low-side NFET. Use gate resistors for wave-shaping	21
WOUT VOUT UOUT	27 31 35	TYPE 7 TYPE 7 TYPE 7	Current return path for high-side predriver and reference for high-side short-circuit shutoff	21
WH VH UH	28 32 36	TYPE 7 TYPE 7 TYPE 7	Predriver output pin for the high-side NFET. Use gate resistors for wave-shaping	21
VDH	37	TYPE 14	Sense input for supply voltage and short-circuit detection of high-side power Fets. Connect through 100 Ω resistor to common drain of the power bridge	21
PGND	38	TYPE 10, 11	GND pin for the charge pump	
VGL	39	TYPE 10	Power supply pin for low-side predriver. Connect decoupling capacitor between this pin and GND	19
CHP	40	TYPE 11	Power supply pin for high-side predriver. Connect decoupling capacitor between this pin and VS	19

LV8961HUW

PIN DESCRIPTION (continued)

Pin Name	Pin No	TYPE	Description	Page
CP1N	41	TYPE 10	Charge transfer pin of the Charge pump (1N). Connect capacitor between CP1P and CP1N	19
CP1P	42	TYPE 10	Charge transfer pin of the Charge pump (1P). Connect capacitor between CP1P and CP1N	19
CP2P	43	TYPE 11	Charge transfer pin of the Charge pump (2P). Connect capacitor between CP2P and CP2N	19
CP2N	44	TYPE 11	Charge transfer pin of the Charge pump (2N). Connect capacitor between CP2P and CP2N	19
TEST	45	TYPE 15	Factory test pin. Connect to GND	
VS	46		Power supply pin	
WAKE	47	TYPE 6	WAKE pin. "H" = Operating mode, "L" or "Open" = Sleep mode. In Sleep mode all predrivers are high impedance. To protect the power stage, pull-down resistors on the gate lines may be required	18
EN	48	TYPE 3	Motor stage Enable pin. "H" = Normal enabled mode; "L" or "Open" = Standby mode. In Standby mode all predrivers are driven low. Motor freewheeling	18

ABSOLUTE MAXIMUM RATINGS

Parameter	Pins	Ratings	Unit
Supply Voltage	VS	–0.3 to 40	V
Sense Input for Supply Voltage	VDH	–0.3 to 40	V
Charge Pump Voltage (High Side)	CHP	–0.3 to 40	V
Charge Pump Voltage (Low Side)	VGL	–0.3 to 16	V
Logic Power Supply	VR3I, VR3O	–0.3 to 3.6	V
5 V Regulator Voltage	VCC	–0.3 to 5.5	V
Digital I/O Voltage1	WAKE, EN	–0.3 to 40	V
Digital I/O Voltage2	CSB, SCLK, SI, LVPIN, TEST	–0.3 to 5.5	V
Digital Output Voltage	DIAG, FG, SO, RXD	–0.3 to 40	V
High Voltage PWMIN Voltage	HVPIN	–10 to 40	V
RF Input Voltage	RF	–3 to 3.6	V
RFSENS Input Voltage	RFSENS	–0.3 to 1.0	V
TH Input Voltage	TH	–0.3 to 3.6	V
Voltage Tolerance	UOUT, VOUT, WOUT, COM	–3 to 40	V
High-side Output	UH, VH, WH	–3 to 40	V
Low-side Output	UL, VL, WL	–3 to 16	V
Low-side Source Output Voltage	SUL, SVL, SWL	–3 to 3.6	V
Voltage between HS Gate and Phase	UH–UOUT, VH–VOUT, WH–WOUT	–0.3 to 40	V
Voltage between LS Gate and Source	UL–SUL, VL–SVL, WL–SWL	–0.3 to 16	V
Output Current	UH, VH, WH, UL, VL, WL pulsed (duty 5%)	50 400	mA
Open Drain Output Current	DIAG, FG, SO, RXD	10	mA
Thermal Resistance ($R_{\theta JA}$)	with Board (Note 1)	47	°C/W
ESD Human Body Model	AEC Q100–002	2	kV
ESD Charged Device Model	AEC Q100–011	750	V
Storage Temperature		–55 to 150	°C
Junction Temperature		–40 to 150	°C
	(Note 2)	150 to 175	°C

Stresses exceeding those listed in the Maximum Ratings table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.

1. 76.2 × 114.3 × 1.6 mm, glass epoxy board.
2. Operation outside the Operating Junction temperature is not guaranteed. Operation above 150°C should not be considered without a written agreement from **onsemi** Engineering staff.

ELECTRICAL CHARACTERISTICS

(Valid at a junction temperature range from -40°C to 150°C , for supply Voltage $6.0\text{ V} \leq \text{VS} \leq 28\text{ V}$. Typical values at 25°C and $\text{VS} = 12\text{ V}$ unless specified otherwise)

Parameter	Symbol	Condition	Min	Typ	Max	Unit
Supply-voltage Range	VS	Normal mode	6	12	28	V
		Device fully functional	5.5	–	28	V
		Full logic functionality, driver stage off	4.5	–	40	V
Supply Current into VS	I_{s1}	V3RO = V3RI EN = L	–	15	25	mA
	I_{s2}	Sleep Mode	–	40	80	μA
Operational junction Temperature	Topj		-40	–	150	$^{\circ}\text{C}$

OUTPUT BLOCK (UH, VH, WH, UL, VL, WL)

Low-side Output On-resistance 1	RON(L1)	“L” level $I_o = 10\text{ mA}$	–	6	15	Ω
Low-side Output On-resistance 2	RON(L2)	“H” level $I_o = -10\text{ mA}$	–	12	22	Ω

Product parametric performance is indicated in the Electrical Characteristics for the listed test conditions, unless otherwise noted. Product performance may not be indicated by the Electrical Characteristics if operated under different conditions.

3. Not tested in production. Guaranteed by design.

DETAILED FUNCTIONAL DESCRIPTION

The LV8961H integrates full sensorless brushless DC motor commutation and Proportional/Integral (PI) speed control. A robust startup algorithm combined with OTP registers for important system parameters make this IC a solution of choice for many BLDC applications which need to turn a motor in one direction only such as pumps, fans, etc.

Building a BLDC application with the LV8961H is even simpler than building a DC motor. Only a PWM pulse train is necessary to control the motor – either directly or via speed control. Switch-only applications are also possible. Speed and error information can be fed back to the control unit via FG and DIAG outputs.

If more complex operation and flexibility are required the LV8961H can be combined with a small microcontroller. The LV8961H implements motor commutation and includes all necessary support circuitry for the microcontroller such as:

- 5 V / 3.3 V Power supply
- Integrated watchdog timer
- External Temperature Sensor

In case of system errors such as a missing control signal, or a watchdog error, the LV8961H includes auto-run settings. If one of those errors occur and connection to the microcontroller is lost, the motor can continue running at a predefined fixed duty cycle of 25%, 50%, 75% or 100% and TAG_L or TAG_H.

Motor Commutation

Motor position is detected using the BEMF of the un-driven phase of a rotating three-phase motor relative to its neutral point connected to COM. BEMF monitoring can be detected at 2 points in each phase of U/V/WOUT, and there are 6 zero-crossing signal in 3 phase in total with 6 un-driven windows. Once an adequate BEMF level has been detected voltages applied via PWM to the other two phases of the motor maintain rotation. The digital equivalent of the BEMF signal appears at FG.

Two different PWM patterns can be selected via register SLMD to match motors with trapezoidal or sinusoidal BEMF.

Figure 7. Trapezoidal vs. Sinusoidal Drive
(CH1, 2 = U, V Phase Voltage, CH3 = FG, CH4 = U Phase Current)

With sinusoidal drive, each phase is driven with 6 windows for BEMF monitoring. This results in sinusoidal drive current with lower total harmonic distortion, reducing both torque ripple and noise. Trapezoidal drive results in a higher voltage across the motor phases and may be preferable for high torque and high speed operation.

Rotor Position Detection

The rotor position is detected with BEMF zero-cross timing. To detect the BEMF, the short window is opened by making the phase current zero or the phase float. Four types of the window mode are provided.

- 6-window mode
All zero-crossings (rising and falling) for all three phases

will be detected by opening 6 windows per electrical cycle. This offers increased robustness at the expense of increased current waveform distortion. At the startup, this 6-window mode is automatically selected.

- 3-window mode
One rising zero-crossing for each phase will be detected by opening 3 windows per electrical cycle. The same waveform is applied to the three phases.
- 1-window mode
One rising zero-crossing in phase U will be detected by opening a window only in phase U. Therefore, the current waveform distortion will be minimized for the other phases.

- 2-window mode

A rising- and a falling zero-crossing in phase U will be detected by opening 2 windows per electrical cycle only in phase U.

BEMF Window Timing

Figure 8 shows a timing chart of the BEMF window with simplified phase voltage and current waveform illustrations.

In this example (3-window mode), we will introduce two important timing parameters: MSKRSTNUM0 and MSKRSTNUM1:

Figure 8. BEMF Window Timing Parameters

(1) MSKRSTNUM0_***

Where, *** is ONE (for 1-window mode), TWO (for 2-window mode), THR (for 3-window mode), SIX (for 6-window mode), or INI (for startup 6-window mode).

MSKRSTNUM0 defines the time from the beginning of the BEMF detection window (reserved for that phase) until the moment where the phase output turns off (= start of the HiZ window).

$$\begin{aligned} \text{MSKRSTNUM0_THR}[3:0] &= x \\ x < 8 &\rightarrow (15 + x * 3.75) \text{ deg} \\ x \geq 8 &\rightarrow (41.25 + (x - 7) * 1.875) \text{ deg} \end{aligned}$$

Example:

$$x = 4 \rightarrow (15 + x * 3.75) \text{ deg} \rightarrow (15 + 4 * 3.75) \text{ deg} = 30 \text{ deg}$$

(2) MSKRSTNUM1_***

Where, *** is ONE (for 1-window mode), TWO (for 2-window mode), THR (for 3-window mode), SIX (for 6-window mode), or INI (for startup 6-window mode).

MSKRSTNUM1 is a blanking (or ignoring) period from the start of the Hiz window defined by MSKRSTNUM0

until BEMF sensing. This blanking time prevents faulty zero-cross detection due to the flyback caused by the window opening.

$$\begin{aligned} \text{MSKRSTNUM1_THR}[3:0] &= x \\ ((x + 1) + 1.875) \text{ deg} \end{aligned}$$

Example:

$$x = 2 \rightarrow ((x + 1) + 1.875) \text{ deg} \rightarrow ((2 + 1) + 1.875) \text{ deg} = 5.625 \text{ deg}$$

These window parameters are used commonly with the sinusoidal waveform shaping mode and trapezoidal waveform shaping mode.

Table 1.

WINDSEL	The Number of Window		Window Timing Parameters
	SLMD = L Trapezoidal	SLMD = H Sinusoidal	
0	6	6	MSKRSTNUM1_SIX MSKRSTNUM0_SIX
1	6	3	MSKRSTNUM1_THR MSKRSTNUM0_THR
2	6	2	MSKRSTNUM1_TWO MSKRSTNUM0_TWO
3	6	1	MSKRSTNUM1_ONE MSKRSTNUM0_ONE

Maximum Motor Speed

The maximum physical motor speed of the application is limited by the internal clock to approximately 48000 electrical RPM. If this is exceeded the LV8961H coasts the motor until BEMF detection and drive can resume.

Lead Angle Setting

LV8961H can adjust the lead angle according to the output Duty as depicted in Figure 9. It is set by the registers LASET_L, LASET_H and LASET_LIM.

LASET_L sets lead angle when the output duty is 0%, and LASET_H sets lead angle when the output duty is 100%.

And then LASET_LIM sets the upper limit when an application requires it.

Figure 9. Lead Angle adjustment

Motor Startup

BEMF is used for rotor position sensing but for BEMF generation the motor has to be rotating. A stopped motor will initially be driven open-loop until BEMF can be detected.

Open-loop operation is motor parameter dependent. The most critical parameters depend on load and motor inertia: initial commutation frequency and PWM duty cycle (which affects motor flux density).

In the LV8961H, the initial commutation frequency is programmed with register STOSC. Flux density is regulated by limiting startup current with a current ramp. During this ramp the current limit is increased in 16 steps from 0 to the maximum current defined by the external shunt. The ramp time from 102 ms to 6.55 s is defined in register SSTT. Register CLREFEN_STOP allows to disable the current ramp if necessary.

Fixed motor speed will be applied until either a valid BEMF has been detected in all three phases or the startup timer expires.

Motor Lock

This timer begins after the end of the current ramp and can be programmed from 400 ms to 6.4 s in register CPTM. If the timer expires a locked rotor error is flagged. In automatic retry mode, the LV8961H will restart after standby mode for time of eight times of CPTM.

Motor Connect Open Detection

When the motor cannot be started for a certain period of time and it is in the startup mode, this IC flows current to each coil, then determines IC is in a constraint state when current flows, or an open state when no current flows. The detection time for the current to flow can be selected by OPDTM register.

Spin-up of Rotating Motors

The LV8961H can perform freewheeling detection before applying the open-loop spin-up algorithm described above. If the motor is already turning in the right direction the IC will continue with closed-loop commutation. If the motor is turning in the wrong direction, the IC will wait for the motor to stop and then perform open-loop startup.

There are two scenarios where this behavior might not be desirable:

1. Fast Startup is required
Freewheeling detection takes up to one electrical revolution of the motor, which may be unacceptable for some applications. In this case freewheeling detection can be disabled by setting FRREN
2. Windmilling backwards
Should the motor be driven by some external force as it is freewheeling in the wrong direction the LV8961H will potentially wait forever. Should startup under these conditions be required, freewheeling detection must be disabled as well

Chip Activation, Shutdown and System States

After power up of VS and WAKE above 2.5 V the LV8961H wakes up. Standby mode is entered after VS has exceeded 5.5 V (min.).

A high level on WAKE activates the IC from sleep mode which enables the internal linear regulator at V3RO. Once the voltage on V3RO as sensed on V3RI has passed the

power on reset (POR) threshold the system oscillator starts, and after 32 counts of the system clock (1.6 μ s typical) releases the internal digital reset which simultaneously starts the external regulator VCC and the charge pump, and loads the system register contents from OTP into the internal registers. During the entire wake-up sequence of 8 ms (typ.) DIAG is masked for charge pump and VCC undervoltage. After wake-up is complete, the IC enters Standby mode and DIAG is activated to display internal errors. During Standby mode full SPI access is possible.

A high on EN takes the LV8961H from Standby to Normal mode. Normal mode allows motor control and SPI access is limited. A low on EN disables the motor stage regardless of the PWM input and returns the part back to Standby mode.

The IC is shut down by taking WAKE to low level. WAKE has priority over the state of EN, if EN hold functionality is desired; it needs to be implemented with an external diode from EN to WAKE.

System States

LV8961H has three operating modes. The operating modes are controlled by WAKE and EN.

Sleep Mode

Sleep mode is a power saving mode. All circuits are powered down, charge pump is inactive and the SPI port is unusable. Activating WAKE allows the transition from the sleep mode to either Standby or Normal mode.

Standby Mode

In Standby mode the OTP content has been transferred into the main registers. In this mode all outputs are turned off. Any internal writable register that is not locked can be configured by SPI interface.

Normal Mode

In normal mode, outputs can be controlled and all blocks are active. All registers can be read through the SPI interface.

Mode	WAKE	EN	Internal Bias	Logic	VCC	Charge Pump	Drivers
Sleep	L	x	Disable	Reset	Disable	Disable	High-Z
Standby	H	L	Enable	Active	Enable	Enable	Low
Normal	H	H	Enable	Active	Enable	Enable	Enable

Supply Voltage Transients

The LV8961H is well suited to operate during typical automotive transients. It is fully functional during start-stop transients, as it maintains all specified parameters for supply voltages from 6 V < VS < 28 V. If the supply voltage falls below 5 V, for example during cold cranking, undervoltage error is flagged, but digital functionality is maintained until the internal regulator falls below its undervoltage lockout level of 2.2 V. The VCC regulator must be configured for 3.3 V if low transient operation is desired.

If overvoltage protection is enabled in MRCONF8 an overvoltage error is indicated if the supply rises beyond 28 V(min). In both under- and overvoltage error modes, the

power stage drivers UH, VH, WH and UL, VL, and WL go low, turning the external power stage high impedance and letting the motor freewheel. The LV8961H will re-engage the motor after conditions have returned to normal.

System Power Supplies

Three power supplies are integrated into the LV8961H:

- An internal 3.3 V regulator provides power to the digital and interface section
- The VCC regulator can be configured to provide 5 V or 3.3 V to an external processor and other loads

- A two-stage charge pump allows 100% duty cycle operation and maintains full enhancement to the power stage at low input voltages

Internal Regulator V3RO, V3RI

The internal regulator is supplied from VS and provides 3.3 V at V3RO. V3RI is connected to the power supply inputs of the control- and logic circuit blocks. V3RO and V3RI need to be connected externally and decoupled to the GND plane for stability. V3RO should not be connected to external loads.

VCC Regulator

The VCC regulator may power external loads, VCC becomes active during Standby mode and can be configured via register REGSEL to provide 5 V or 3.3 V. **WARNING:** the microcontroller can be damaged if the wrong REGSEL value is selected. Undervoltage error is flagged if the output voltage drops below VCLV5 in 5 V operation, or VCLV3 in 3.3 V operation.

The VCC regulator can be enabled or disabled with register VCEN.

Charge Pump Circuit for CHP and VGL

LV8961H has an integrated charge pump circuit for low-side and high-side predriver supply. Low-side drive voltage at VGL is 12 V(typ.) and high-side drive voltage at CHP is VS + 12 V(typ.). For functionality see Figure 10.

Undervoltage protection for the low-side drivers activates if VGL falls below VGLLV in which case the output FET's will be turned off and VGL undervoltage error is flagged in register MRDIAG. Overvoltage protection for the high-side drivers activates if VS becomes greater than 28 V(min). In that event the driver stage is disabled, overvoltage error is flagged in register MRDIAG, and both VGL and CHP are discharged to prevent output circuit destruction.

The charge pump circuit operates nominally at 52.1 kHz. A SSCG function is provided to add a spread-spectrum component for EMI reduction.

Figure 10. Charge Pump Circuit

INPUT PWM and SPEED CONTROL

The LV8961H provides three speed control methods through the input PWM signal:

1. Indirect PWM translation
2. Closed-loop speed control
3. Direct register command

Indirect PWM Translation

This is the preferred mode for stand-alone operation. The frequency range has two modes, high and low frequency. In the high frequency mode, it corresponds to frequency input up to 18.5 kHz. In the low frequency mode, it is limited to the frequency input up to 1 kHz, and when the frequency input is above 1 kHz, it is ignored. Frequency mode can be configured in high frequency mode by setting register PWMF to 1. In both modes the input PWM signal is compared against minimum PWM frequency thresholds to allow for more robust operation. Frequencies below 5.3 Hz (typ.) are considered as 0% or 100% duty cycle (no frequency).

The duty cycle of the PWM input signal is measured with a resolution of 10 bits. There is an inherent delay to detect and utilize this duty cycle information. It is the delay time from input PWM input signal to output PWM. The delay time is determined by

$$T_{PWM} + 19.8 \mu s \text{ (max.)}$$

Where, T_{PWM} is the period of the PWM input signal. 19.8 μs is fixed value.

If faster startup is necessary, see section “[Fast Startup](#)” below. If no frequency is detected after 210ms (typ.) the PWMPO flag is set in system warning register MRDIAG1. Even without PWM input the LV8961H can run as described below in section “[Fast Startup](#)”.

If a valid frequency was detected, the LV8961H evaluates the input duty cycle and translates it into an output duty cycle as shown in Figure 12. The output PWM frequency is fixed to 19.5 kHz (typ.).

Figure 12. Duty Cycle Translation

Input duty cycles lower than the minimum Duty setting by DUTY_L register are considered a motor-off command and

will also reset the error registers. Input duty cycles higher than the maximum Duty setting by DUTY_H register are considered a full drive command. Input to output duty cycle translation is described by the following formula:

	0	$0 \leq d_{IN} \leq DUTY_L$
$d_{OUT} =$	$\frac{100}{DUTY_H - DUTY_L} \times (d_{IN} - DUTY_L)$	$DUTY_L < d_{IN} < DUTY_H$
	100	$DUTY_H \leq d_{IN} \leq 100$

Closed-loop Speed Control

For stand-alone operation, the LV8961H offers a PI controller for motor speed which is activated by clearing bit SCEN. Frequencies below 5.3 Hz(typ.) are considered as 0% or 100% duty cycle (no frequency). The output PWM frequency is fixed to 19.5 kHz (typ.).

LV8961H provides Linear characteristic target speed setting as shown in Figure 13.

Direct Register Command

LV8961H allows user to access the register directly, which is connected to the control logic, and set the PWM duty cycle command from the PWMDTIN register. This mode can be configured by setting register SPIINSEL to 1. Also, FG frequency information can be obtained from the STATUS register by setting register STATSEL to 0h, and It can minimize delay that occurs when the PWM frequency is low.

Figure 13. Target Speed by Input PWM Duty Cycle

The Control Algorithm

The LV8961H controls the motor speed by comparing the selected target speed to the actual motor speed and incorporating a PI controller with configurable gains for the P, I and T components which are stored in register MRSPCT7, MRSPCT8 and MRSPCT9 respectively.

Ramping of Speed Control Values

While tight control is required for optimal speed tracking, it may be undesirable during large input changes as it may

lead to sudden supply loading, increasing noise and motor wear. To limit the slope of the control signal, register USTEPSEL and DSTPSEL imposes a ramp on an input step to slew the speed response of the motor.

Decreasing motor speed too fast results in energy recuperation back into the system. To limit overvoltage

during energy recuperation, the variable DWNSET allows to prevent energy recuperation entirely by switching the synchronous rectification off.

Figure 14. PWM Command Flow and Related Registers

Fast Startup

It may be desirable to have the motor start immediately after EN goes high and not wait for PWM input duty cycle evaluation. Two register settings enable motor operation during this evaluation time: bit PDTC determines if the motor should be running during this time at all, and PDTSEL selects a motor duty cycle of 25, 50, 75 or 100%. This is used as the initial value of the duty cycle command for the closed-loop speed control mode. To guarantee smooth transition from fast startup to PWM operation it is important to apply a comparable external PWM duty cycle at startup.

Abnormal Duty Cycle Operation (100% or 0%)

For normal duty cycle controlled operation the PWM signal is expected to have a frequency between 5.3 Hz or more. If no frequency is detected, the LV8961H will flag PWMPO error and enter 0% or 100% duty cycle mode depending on the level of the PWM signal (all low or all high). Operation during this mode can be selected to be either no motor operation, or motor operation at a fixed motor duty cycle of 25, 50, 75 or 100% and TAG_L or TAG_H as defined by the variables FLSEL or ZPSEL. These PWM values do not enter into the speed control loop.

Limit the Amount of Change of Output Duty

The register DDUTYSEL allows to limit the amount of change in output duty to avoid sudden acceleration and deceleration.

Speed Feedback FG

The motor speed is shown at open drain output FG where the transitions are direct representations of the BEMF signal transitions on the motor. The relationship between motor rotation and FG pulses is defined in register FGOF.

Fault Output DIAG

A low on open drain output DIAG indicates a system fault and a shutdown of the driver stage. Per default all system faults self-recover when the fault condition is removed. For some potentially destructive faults such as overcurrent, FET short-circuit and locked rotor conditions, it is possible to latch the fault condition. For more information on system diagnostics see section “[System Errors and Warnings](#)”.

High Voltage PWM Interface

The PWM interface translates a VS level signal with a threshold of 50%(Typ) VS to a digital signal appearing at RXD pin. This signal can be used for input PWM translation from outside units to the microcontroller.

Predriver Circuit

The predriver circuit of the LV8961H includes 3 half-bridge drivers which control external NFETs for the motor phases U, V and W. The high-side drivers UH, VH, WH switch their gate connection either to CHP or the respective phase connection UOUT, VOUT and WOUT. The low-side drivers are switched from VGL to the corresponding source connection SUL, SVL, SWL. Both high- and low-side switches are not current controlled. Slope control has to be implemented with external components.

Current shoot through protection of the bridge drivers is implemented by a dead time counter that delays the turning-on of the complementary switch. The dead time can be programmed from 200 ns < t_{FDTI} < 6.4 μs into 5bit parameter FDTI.

To protect against external shorts the drain–source voltage of the active external Power FETs is monitored as well. 4 bit register FSCDL selects a short–circuit shutoff voltage $100\text{ mV} < V_{\text{FSCDL}} < 1.6\text{ V}$. To suppress false triggering during the rising edge of FET activation, FSCDT selects the masking time.

Current Limit and Overcurrent Shutoff

An integrated current sense amplifier implements current limiting and overcurrent shutoff by measuring the motor phase current across a single shunt between RF and RFSENS.

Figure 15 shows a summary of the current limit and the overcurrent shutoff, and the descriptions for each function are in the following sections.

In Sleep mode, the high– and low–side gate outputs of each U, V, W phase become High Z.

A 100 k Ω pull–down resistor is built–in between UH and UOUT of the high–side predriver output so that the gate and source of the external FET do not become High Z.

The low–side output also has a built–in 100 k Ω pull–down resistor between the UL and SUL terminals (similar for V and W phases).

An external resistor (typ. 100 k Ω) is visible in the application circuit between the gate and source of the FET.

Cycle–by–cycle Current Limit

If the voltage between RF and RFSENS exceeds VRF1, the active bridge is turned off until the next PWM period. VRF1 can be selectable 100 mV(Typ) or 50 mV(Typ) by register CLSEL. To suppress switching transients a current limit blanking time $0.2\text{ }\mu\text{s} < t_{\text{CLMASK}} < 3.2\text{ }\mu\text{s}$ can be programmed into register CLMASK.

During soft start this current limit is ramped from 0 to VRF1 in 16 steps during a programmable time 102 ms $< t_{\text{SSTT}} < 6.55\text{ s}$ as defined in register SSTT.

Overcurrent Shutoff

If the bit OCPEN is set and the voltage between RF and RFSENS exceeds VRF2, the LV8961H goes into overcurrent shutoff and all predrivers are driving low turning the power FETs high impedance. VRF2 can be selectable VRF1 + 25 mV, +50 mV, +75 mV and +100 mV by register OCSEL. To suppress switching transients an overcurrent shutoff blanking time $0.2\text{ }\mu\text{s} < t_{\text{OCMASK}} < 3.2\text{ }\mu\text{s}$ can be programmed into register OCMASK.

Table 2. SUMMARY OF POWER STAGE PROTECTIONS

Current	Purpose	Flag	Sense point	Threshold	Turn–off	Recovery
Cycle–by–cycle	Limiter	CLDO	Sense Resistor VRF	VRF1 100 mV or 50 mV	PWM FET	Next PWM cycle
Short to VS	Protector	OCPO	Sense Resistor VRF	VRF1+25 mV, +50 mV, +75 mV and 100 mV	All FET	50 ms later
		FSPO	FET VDS MOUT–SXL	Configurable		
Short to GND	Protector	FSPO	FET VDS VDH–MOUT	Configurable	All FET	50 ms later

Figure 15. Current Limit vs. Overcurrent Shutoff

Temperature Sensing

The LV8961H measures the die temperature and implements internal thermal warning and shutoff. It is also possible to protect external devices by monitoring the voltage at pin TH. Internal and external overtemperature can shut down the driver section.

Internal Overtemperature Measurement

A thermal warning is issued if the internal temperature of the device reaches approximately 25°C below the overtemperature shutoff level. The shutoff level is selected by bit TSTS as 150°C or 175°C(min).

External Overtemperature Shutoff

An analog comparator triggers external overtemperature error if the voltage at pin TH falls below the two bit programmable level $0.2\text{ V} < V_{\text{THTH}} < 0.35\text{ V}$ as defined by register THTH. For external temperature measurement connect a resistor between V3RO and TH and an NTC between TH and AGND. The programmed threshold voltage at V_{THTH} should be reached at the intended thermal shutdown temperature of the external component to be protected. During the overtemperature condition, the predrivers are disabled and a flag, THPO in MRDIAG0 is set.

Figure 16. Example Circuit for External Temperature Sensing

Watchdog Operation

The LV8961H includes a watchdog timer to monitor a companion microcontroller and disable the motor if the

microcontroller stops working properly. Bit WD TEN enables and disables the watchdog timer. Access to this bit can be blocked – see section “OTP Register” for details. The enabled watchdog will issue an error whenever the watchdog time $1.6\text{ ms} < t_{\text{WDT}} < 102.4\text{ ms}$ expires. A write of 00h to register MRRST resets the watchdog timer.

A watchdog timeout can result in either a motor stop, or motor operation at four predefined duty cycles of 25%, 50%, 75% or 100% and TAG_L or TAG_H as defined by WDTSEL. The duty cycle is directly applied to the power stage, not through the speed selection registers. The microprocessor is not reset.

System Errors and Warnings

All system errors and most warnings cause a transition on DIAG. The polarity of this transition can be selected in bit DIAGSEL. The ability of stand-alone applications without microcontroller to react to errors and warnings is limited. For this case various auto-retry strategies are implemented.

If a companion microcontroller exists, more complex error handling is possible and DIAG should be connected to an interrupt input of the microcontroller. Errors that may cause serious damage such as short-circuit, overcurrent and locked rotor can be latched by enabling the corresponding latch bit in MRCONF9. In this case the LV8961H will keep the output stage disabled until the latch is cleared by one of the following actions:

- Power on reset
- EN low
- Input the output duty 0% or 0 rpm command
- SPI write of FFh to MRRST

If bit DLTO is set ONLY latched errors will cause a transition of DIAG. To detect the other less serious errors and warnings, the diagnostic registers MRDIAG0 /MRDIAG1/MRDIAG2 have to be read regularly via SPI access.

Table 3. ERROR AND WARNING DIAGNOSTIC REGISTER (Note 4)

ADDR	Bit	Error	Description	Enabled Set	Latched Set	Self-Recovery Timing
0201h	0	OCPO	Overcurrent Error	OCPEN	OCPLT	After 50 ms (typ.) the motor will restart
0201h	1	VSLVPO	VS Undervoltage	N/A	N/A	Motor is restarted when voltage recovers

4. See register MRCONF 7 to 12 for error and warning activation, masking and latching options.

Detection of Loss of Commutation Synchronization

Three methods are provided to detect the loss of commutation synchronization which is significant for sensorless motor control applications.

1. Open load
2. Abnormal rotational speed change
3. Locked rotor

They are explained in the following sections.

Open Load Detection

LV8961H can detect an open motor phase connection by means of setting OPOEN = 1.

When this function is enabled, then after the detection of a blocked rotor (CPO=1), a testcurrent is briefly pulsed from UH to VL, from VH to WL and from WH to UL. The current will increase and stop when the current limit is reached (outputs are switched off). When the current limit is not reached within the time set by OPDTM, the outputs are switched off and an open connection is assumed. However, a motor phase is considered open (bit OPO=1) only if both

sequences related to that motorphase don't reach in time the current limit. Therefore it is important to set OPDTM sufficiently long.

It can be checked which U, V, W connector is open by reading the status register. One connector opening of U, V, W can be distinguished, but when two or three openings overlap, it is judged that everything is open so it cannot be distinguished what is not open. Also, if only one of UH-VL, VH-WL, WH-UL combinations don't reach the current limit, it is judged that all phases are connected.

When automatic recovery mode is set, OPO returns to 0 when the time set in the CPTM register (the constraint protection detection time multiplied by 8) has elapsed. When latch mode is set, OPO returns to 0 by EN = L input, PWM 0% input, or MRRST command.

Because the open load detection is performed after the constraint protection detection, CPO = 1 is output.

Figure 17 shows an example where automatic recovery mode is set and phase-V is detected to be open.

Figure 17. Timing Chart of OPO

Abnormal Rotational Speed Change Detection

The abnormal rotational speed change detection is activated for acceleration through bit FGERACCEN and for deceleration by means of FGERDECEN.

An abnormal acceleration is detected if the number of detected BEMF zero-crossings immediately after the mask is opened is equal or larger than the number represented by FGERACC.

An abnormal deceleration is detected if no zero-crossings are observed during the time represented by FGERDEC (Table 4).

If it is judged that the rotation speed is abnormal, LV8961H restarts from free-run detection after the recovery time set by RCVTM has elapsed.

Upon detection of abnormal rotational speed change, all predriver outputs are switched off and bits FGERACCO resp. FGERDECO are set. They will reset when the recovery time (RCVTM) elapses.

The protection state also returns to normal state by either EN = L input, sensorless logic reset pulse by MRRST.

When FGERACCEN/FGERDECEN = 0, although the rotation speed abnormality is detected, state transition to the protection state does not occur.

Table 4. FGERDEC SETTING

FGERDEC[2:0]	Detection Setting
0	(previous 60 electrical degrees period) × 1.25
1	(previous 60 electrical degrees period) × 1.5
2	(previous 60 electrical degrees period) × 1.75
3	(previous 60 electrical degrees period) × 2
4	(previous 60 electrical degrees period) × 3
5	(previous 60 electrical degrees period) × 4
6	(previous 60 electrical degrees period) × 6
7	(previous 60 electrical degrees period) × 8

Figure 18. Timing Chart of SPCO

Locked Rotor Detection

Open-loop startup continues for the time programmed into CPTM (MRCONF6[6:3]). If no BEMF is detected during that time a locked rotor error is indicated.

Table 5. MRCONF6

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0106h	MRCONF6	0	CPTM[3:0]				THTH[1:0]		TSTS

CPTM[3:0] : Constrained movement Protection Time

The locked rotor is detected by counting the time LV8961H is in the startup mode without BEMF detection. If consecutive seven BEMF zero-crossings are not detected within the time programmed into CPTM register, the driver outputs are turned off and the locked rotor is flagged.

In auto-recovery mode, the motor will remain off for the open-loop startup timeout duration multiplied by 8, before another startup is attempted.

Detection time has maximum 1 ms error, because it is sampled by 1 ms clock.

Table 6. MRDIAG0

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0201h	MRDIAG0	CPO	THPO	FSPO	VGLLVPO	CHPLVPO	VSOVPO	VSLVPO	OCPO

CPO : Constrained movement Protection Output

If no BEMF is detected during the entire open-loop startup time as programmed in CPTM, then either the rotor

is blocked, or startup parameters are not correct. The drivers will be disabled.

SPI Interface

In the LV8961H the SPI interface is used to perform general communications for status reporting, control and programming. The SPI format is MODE-0 MSB first.

SPI communication with the LV8961H follows the established industry standard practices. Data is transferred MSB first, and it is captured at the rising edge of the clock which stays in logical low during idle. Figure 19 shows LV8961H SPI format. When the first SI bit “R/W” is LOW, the register data will be transferred from LV8961H to the master device. When “R/W” is HIGH, the register data is transferred from the master device to the LV8961H register.

The address data is composed of 16 bits and has a function of accessing from the address specified by the data Length [2:0] setting to the address of continuous 8 bytes by one communication. In addition, the LV8961H offers CRC

check feature to ensure SPI communication. Therefore, Format 1 in Figure 19 requires a minimum 5 bytes data length with one access. Format 2 in Figure 19 is prepared to access with a short data length. It can be used for addresses requiring access in a short time and is set by the data BASEL[3:0].

When the repeating access to the same register access is required, a shorter bit-length alias of the target address can reduce the total length of the SPI serial communication data train. In LV8961H, the base address pointers are provided as an alias of the full-bit address. The base address can be specified with the register “BAREG[15:0]”. And, BAREG[15:0] is activated as the base address pointer when the bit-field “BASEL[3:0]” value in the SPI serial data train is 15. Without BAREG setting, 14 preset base addresses,

which might be read or written frequently and repeatedly,

are provided. The following table shows the those addresses selected by the bit-field BASEL[3:0].

Table 7.

BASEL[3:0]	Register name	Register address	Description
0	NA	NA	Direct addressing in full-bit
1	MRACK0	0000h	55h fixed value read-only
2	MRSPCT0	0002h	Current control parameters
3	MRSPCT1	0003h	Lead angle parameters
4	MRSPCT3	0005h	Startup parameters
5	MRSPCT7	0009h	Speed control PI parameters
6	MRSPCT10	000Ch	Speed control parameters
7	MRSPCT11	000Dh	Speed curve parameters
8	MRSPCT19	0015h	BEMF window parameters
9	MRDIAG0	0201h	Diagnosis flags
10	MRSTAT0	0205h	Status
11	MRRST	0300h	Reset related
12	MRCTL0	0301h	PWM duty cycle input
13	MRCTL2	0303h	commutation parameter
14	MRCTL5	0306h	STATUS selection
15	Selectable	Selectable	Any register selected with the register

The base address is the first one, and the consecutive multiple address can be accessed by setting the bit-field "LENGTH[2:0]".

For example, to write the duty cycle data to the register PWMDTIN[9:0] (located in MRCTL0 0301h and MRCTL1 0302h), the following three data patterns are applicable and typical.

1. Writing twice by one byte (total 64 bits)

Table 8.

1	2	3	4	5	6	7	8	9 to 16	17 to 24	25 to 32
WR	Length			BASEL				Address[15:8]	Address[7:0]	Data LSB
1	0	0	0	0	0	0	0	03	01h	PWMDTIN[7:0]

Table 9.

33	34	35	36	37	38	39	40	41 to 48	49 to 56	57 to 64
WR	Length			BASEL				Address[15:8]	Address[7:0]	Data MSB
1	0	0	0	0	0	0	0	03h	02h	PWMDTIN[9:8]

2. Writing once by two-byte with the full address (total 40 bits)

Table 10.

1	2	3	4	5	6	7	8	9 to 16	17 to 24	25 to 32	33 to 40
WR	Length			BASEL				Address[15:8]	Address[7:0]	Data LSB	Data MSB
1	0	0	1	0	0	0	0	03h	01h	PWMDTIN[7:0]	PWMDTIN[9:8]

3. Writing once by two-byte with the base address (total 24 bits)

Table 11.

1	2	3	4	5	6	7	8	9 to 16	17 to 24
WR	Length			BASEL				Data LSB	Data MSB
1	0	0	1	1	1	0	0	PWMDTIN[7:0]	PWMDTIN[9:8]

Where, the bit sequence of data bytes is;

Table 12.

sequence	1 st	2 nd	3 rd	4 th	5 th	6 th	7 th	8 th
PWMDTIN LSB	[7]	[6]	[5]	[4]	[3]	[2]	[1]	[0]

Table 13.

sequence	1 st	2 nd	3 rd	4 th	5 th	6 th	7 th	8 th
PWMDTIN MSB	NA	NA	NA	NA	NA	NA	[9]	[8]

There are two items to be especially careful of with the general communication scheme:

1. Communications must be full duplex and simultaneous. It is not allowed to send one transaction and then read data on a second transaction as the status register information will be updated on the first transaction and then be out of date for the second. Some systems break transactions into separate read and write operations which is not acceptable with the LV8961H.
2. It is important the system master uses the clock and data polarities and phases as shown above. Both the clock and data on some systems can be

inverted for various reasons but must arrive at the LV8961H per the above drawing. Common errors include SCLK inversion such that the leading edge arrives as a downward transition rather than a rising edge, or having the data to clock phase incorrect. Data phase must be such that the data only changes during a clock falling edge and is completely stable during a clock rising edge. This means a good margin of one half of a bit time exists to eliminate transmission delay hazards.

The first byte returned on all transactions is always the status register, GSDAT, and contains information such as the busy flag during programming operations.

**Format 1 : Normal SPI access format****Format 2 : Short SPI access format****Figure 19. SPI Format**

The header byte structure of the SPI format can be described by the following C language program.

```
enum readwrite {RD, WR};
enum regCount {cnt1, cnt2, cnt3, cnt4, cnt5, cnt6, cnt7, cnt8};
enum baseReg {na, MRACK0, MRSPCT0, MRSPCT1, MRSPCT3, MRSPCT7, MRSPCT10, MRSPCT11,\
  MRSPCT19, MRDIAG0, MRSTAT0, MRRST, MRCTL0, MRCTL2, MRCTL5, BY_BAREG};

union {
  uint8_t bitwise;
  struct {
    baseReg   BASEL: 4;
    regCount  Length: 3;
    readwrite RW: 1;
  };
} header;
```

The checksum (CRC) code of the SPI data train is calculated by the following function.

```
#define CHAR_BIT      8          /* number of bits in a char */
#define MSB_CRC8      (0x4D)    /* polynomial*/

uint8_t GetCRC8_2(uint8_t seed, const void *buff, size_t data_size)
{
  uint8_t *p = (uint8_t *)buff;
  uint8_t crc8;
  int i;

  for (crc8 = seed; data_size != 0; data_size--){
    crc8 ^= *p++;

    for (i = 0; i < CHAR_BIT; i++){
      if (crc8 & 0x80){
        crc8 <<= 1; crc8 ^= MSB_CRC8;
      }
      else{
        crc8 <<= 1;
      }
    }
  }
  return crc8;
}
```

An example SPI communication is shown below. It shows the case that the two bytes from the register MRACK0 within one transaction, using the base address scheme.

```
uint8_t SPI_WR_BUF[32];
uint8_t SPI_RD_BUF[32];

void example_main()
{
    int i;

    header.RW = RD;           /* read */
    header.Length = cnt2;     /* 2 bytes */
    header.BASEL = MRACK0;    /* from MRACK0 */
    Serial.print("Header = ");
    Serial.print(header.bytestwise, HEX);
    Serial.println("h");

    SPI_WR_BUF[0] = header.bytestwise;
    SPI_WR_BUF[1] = 0;        /* dummy data */
    SPI_WR_BUF[2] = 0;        /* dummy data */
    SPI_WR_BUF[3] = GetCRC8_2((uint8_t)0, SPI_WR_BUF, 3);
    Serial.print("CRC = ");
    Serial.print(SPI_WR_BUF[3], HEX);
    Serial.println("h");

    digitalWrite(CSB_pin, LOW);
    for (i = 0; i < 4; ++i)
    {
        SPI_RD_BUF[i] = SPI.transfer(SPI_WR_BUF[i]);
        Serial.print(SPI_WR_BUF[i], HEX); Serial.print("h, ");
        Serial.print(SPI_RD_BUF[i], HEX); Serial.println("h");
    }
    digitalWrite(CSB_pin, HIGH);
}
```

This output is shown below.

```
Header = 11h
CRC = 66h
```

```
WR,   RD
11h, 02h
00h, 55h
00h, AAh
66h, B3h
```

GSDAT Field

Global status is always output to this field. Global status contains following information.

GSDAT[7:0]

Bit 7	6	5	4	3	2	1	Bit 0	
ORBEN	SACF	DIAGS	LATCH	OBSY	SMOD[2:0]			
					0	0	0	Sleep mode
					0	0	1	Device startup time
					0	1	0	Standby mode
					0	1	1	N/A
					1	0	0	N/A
					1	0	1	Normal mode without FG output
					1	1	0	Normal mode with FG output
					1	1	1	Sleep mode
0	x	0	0	0	x	x	x	Normal operation
				1				OTP busy with read/write access
			1					Latched shutdown condition
		1						Failure condition
	0							Last SPI access OK
	1							Last SPI access failed*
1								OTP integrity test mode

The following SPI failures are detectable and reported collectively in GSDAT as general SPI failures:

- Any access to an address which are outside the defined address space
- The number of SCLK transitions is not 16 within one word transfer
- Any access to MRCONF, MRACS, ORCONF, ORACS while OBSY = 1 (during write operations)
- Write access to MRODL register while OBSY=1 (during write operations)
- Write access to any of the main registers after setting MSAENB = 1 (Implies MRxxxx registers are locked)
- Write access to any of the OTP registers after OSAENB = 1 (Implies ORxxxx registers are locked)
- Write access attempt to a read-only or locked register
- SI signal changed at positive edge of SCLK (Incorrect data/sclk phase setup)

SPI Timing

Figure 20. SPI Timing Chart

SPI TIMING

(T_J = -40 to 150°C, V_S = 4.5 to 28 V, Pull-up resistance of SO pin = 2.4 kΩ, Output load of SO pin = 30 pF)

Symbol	Comment	Min	Typ	Max	Unit
Tfck	SCLK clock frequency			500	kHz
Tckp	SCLK high pulse width	950			ns
Tckn	SCLK low pulse width	950			ns
Tcss	CSB setup time	950			ns
Tcsh	CSB hold time	950			ns
Tcsp	CSB high pulse width	1900			ns
Tsis	SI setup time	450			ns
Tsih	SI hold time	450			ns
Tcssod	CSB fall edge to SO delay time			950	ns
Tcksod	SCLK fall edge to SO delay time			950	ns
Tcssoo	CSB fall edge to SO data out time	0			ns
Tcssoz	CSB rise edge to SO High Z out time			950	ns

Register Description

SPI Register Map

The SPI interface allows read access to the entire address space of the main registers. The main registers can only be

written in Standby mode and then only if the write lock bit MSAENB has never been set high.

MRACK0

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0000h	MRACK0	0	1	0	1	0	1	0	1

MRACK0[7:0]: Main Register Access Check

MRACK0[7:0] read data is fixed to 55h

This read-only register is used to check IC and SPI interface. 55h is read from this register in standby and normal mode, FFh during sleep mode.

MRACK1

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0001h	MRACK1	1	0	1	0	1	0	1	0

MRACK1[7:0]: Main Register Access Check
MRACK1[7:0] read data is fixed to AAh

This read-only register is used to check IC and SPI interface. AAh is read from this register in standby and normal mode, FFh during sleep mode.

MRSPCT0 (DEFAULT: 00h)

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0002h	MRSPCT0	0	0	CLSEL	CLDWNOFF	OCSEL[1:0]		CLMSPD[1:0]	

CLSEL: Current Limit threshold SElection

CLSEL=0: Threshold voltage 50 mV

CLSEL=1: Threshold voltage 100 mV

CLDWNOFF: Current Limit semi-powerDoWN OFF

CLDWNOFF=0: function ON

CLDWNOFF=1: function OFF

OCSEL[1:0]: OverCurrent threshold SElection

CLSEL=0

OCSEL[1:0]=0h: Threshold voltage 75 mV

OCSEL[1:0]=1h: Threshold voltage 100 mV

OCSEL[1:0]=2h: Threshold voltage 125 mV

OCSEL[1:0]=3h: Threshold voltage 150 mV

CLSEL=1

OCSEL[1:0]=0h: Threshold voltage 125 mV

OCSEL[1:0]=1h: Threshold voltage 150 mV

OCSEL[1:0]=2h: Threshold voltage 175 mV

OCSEL[1:0]=3h: Threshold voltage 200 mV

CLMSPD[1:0]: Current LiMit Semi-PowerDown level

CLMSPD[1:0]=0h: 0.1%

CLMSPD[1:0]=1h: 1.3%

CLMSPD[1:0]=2h: 2.5%

CLMSPD[1:0]=3h: 5.07%

MRSPCT1 (Default: 00h)

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0003h	MRSPCT1	0	0	SSTT[5:0]					

SSTT[5:0]: Soft Start Time

SSTT[5:0]=00h: Soft start time 0.102 s

SSTT[5:0]=x: Soft start time $0.102 * (1 + x)$ s

SSTT[5:0]=3Fh: Soft start time 6.55 s

Soft start allows startup of motors with higher inertia by ramping the current. The soft start algorithm divides the

current limit voltage 100 mV (Typ) into 16 sections and increases the value from 6.25 mV to 100 mV to switch over the current limit value. Case of 50 mV, increases the value from 3.125 mV to 50 mV.

MRSPCT2 (Default: 00h)

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]

SLMD: Sinusoidal Mode Driving

SLMD=0: Trapezoidal drive with 120 degrees energization.

SLMD=1: Sinusoidal drive with 6 windows BEMF detection.

This bit selects whether the motor phases are driven with a trapezoidal or sinusoidal signal.

LV8961HUW

LASET_L[4:0]: Lead Angle SETting at Low output duty cycle (0%)

LASET_L[4:0]=00h: Lead angle 0 deg.
LASET_L[4:0]=x: Lead angle (x * 1.875) deg
LASET_L[4:0]=1Fh: Lead angle 58.125 deg.

It is possible to advance the commutation point towards zero-crossing of the BEMF signal. This helps to achieve BEMF field-weakening for higher rotational speeds and to compensate for delays in high speed operation.

MRSPCT4 (Default: 00h)

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0006h	MRSPCT4	0	0	0	LASET_H[4:0]				

LASET_H[4:0]: Lead Angle SETting at High output duty cycle (100%)

LASET_H[4:0]=00h: Lead angle 0 deg.
LASET_H[4:0]=x: Lead angle (x * 1.875) deg
LASET_H[4:0]=1Fh: Lead angle 58.125 deg.

It is possible to advance the commutation point towards zero-crossing of the BEMF signal. This helps to achieve BEMF field-weakening for higher rotational speeds and to compensate for delays in high speed operation.

MRSPCT5 (Default: 00h)

0100h	MRCONF0	FRMD	FRREN	SCEN	PWMF	REGSEL	VCEN	SPCFG	PWMINSEL

FRMD: Forward / Reverse MoDe

FRMD=0: Forward motor rotation

FRMD=1: Reverse motor rotation

FRREN: FRee Running ENable

FRREN=0: Motor will start with a BEMF detection.

FRREN=1: Motor will start open-loop with startup parameters.

SCEN: external Speed Control ENable

SCEN=0: Speed feedback loop is active. RPM is selected from input duty cycle.

SCEN=1: Power stage duty cycle is translated from input duty cycle.

PWMF: PWM input Frequency selection

PWMF=0: Valid PWM input frequency range from 5.3 Hz to 1 kHz.

PWMF=1: Valid PWM input frequency range from 5.3 Hz to 18.5 kHz.

REGSEL: Vcc REGulator SElection

REGSEL=0: VCC output set to 3.3 V.

REGSEL=1: VCC output set to 5 V.

VCEN: Vcc regulator ENable

VCEN=0: VCC is off.

VCEN=1: VCC is active.

SPCFG: Speed feedback loop calculation Period ConFiGuration

SPCFG=0: Calculate per 360 electrical degrees.

SPCFG=1: Calculate per 120 electrical degrees. (Using speed just before 360 electrical degrees)

PWMINSEL: PWM INput pin SElection

PWMINSEL=0: HVPIN is used for PWM input. (High voltage)

PWMINSEL=1: LVPIN is used for PWM input. (Low voltage)

MRCONF1 (Default: 00h)

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0101h	MRCONF1	FLSEL[2:0]			ZPSEL[2:0]			PDTC	PWMON

FLSEL[2:0]: Full Load fallback level SElection (PWM input 100% duty mode)

FLSEL[2:0]=0h,7h: Motor is turned off

FLSEL[2:0]=1h: Motor duty cycle 25%

FLSEL[2:0]=2h: Motor duty cycle 50%

FLSEL[2:0]=3h: Motor duty cycle 75%

FLSEL[2:0]=4h: Motor duty cycle 100%

FLSEL[2:0]=5h: Motor duty cycle is decided by TAG_L setting

FLSEL[2:0]=6h: Motor duty cycle is decided by TAG_H setting

ZPSEL[2:0]: Zero Power fallback level SElection (PWM input 0% duty mode)

ZPSEL[2:0]=0h,7h: Motor is turned off

ZPSEL[2:0]=1h: Motor duty cycle 25%

ZPSEL[2:0]=2h: Motor duty cycle 50%

ZPSEL[2:0]=3h: Motor duty cycle 75%

ZPSEL[2:0]=4h: Motor duty cycle 100%

ZPSEL[2:0]=5h: Motor duty cycle is decided by TAG_L setting

ZPSEL[2:0]=6h: Motor duty cycle is decided by TAG_H setting

PDTC: Pending Detection of a Transition Control

PDTC=0: Fast startup operation is disabled.

PDTC=1: Fast startup operation is enabled.

If PDTC is set, the motor is driven with the duty cycle programmed into PDTSEL, as soon as EN is high.

This feature is bridging the initial 200 ms of operation until a valid PWM duty cycle can be decoded.

PWMON: PWM ON polarity

PWMON=0: PWM input signal is active high.

PWMON=1: PWM input signal is active low.

MRCONF2 (Default: 00h)

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0102h	MRCONF2	FGSTBLMD	FGOF[1:0]		FDTI[4:0]				

FGSTBLMD: Frequency Generator STaBLe MoDe

FGSTBLMD=0: Disable

FGSTBLMD=1: Enable

It affects only for the 6-window mode (WINDSEL = 0). To determine the lead angle timing, the previous BEMF zero-cross interval is sampled. When this function is disabled, the sampling is done every 60 degree electrical cycle. When this function is enabled, the sampling is done every 120 degree, and the previous 60 degree interval will be estimated as 1/2 of 120 degree interval. It ignores the BEMF asymmetric characteristics (or waveform) between rise and fall.

FGOF[1:0]: Frequency Generator Output Frequency (= rotation speed)

FGOF[1:0]=0h: One transition per BEMF detection (FG3)

FGOF[1:0]=1h: One transition per every two BEMF detection (FG3/2)

FGOF[1:0]=2h: One pulse per electrical revolution (FG1)

FGOF[1:0]=3h: One pulse per every two electrical revolutions (FG1/2)

The FG3 signal is a representation of a successfully detected BEMF transition which occurs three times during every electrical revolution.

*FDTI[4:0]: Fet Dead Time*FDTI[4:0]=00h: 6.4 μ sFDTI[4:0]=x: $(6.4 - x * 0.2) \mu$ sFDTI[4:0]=1Fh: 0.2 μ s

During phase switching between supply and GND it is possible for both low- and high-side drivers to be temporarily on at the same time causing large current spikes. Register FDTI defines a dead time during which both drivers will be kept off during these transitions.

MRCONF3 (Default: 00h)

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0103h	MRCONF3	CLMASK[3:0]				OCMASK[3:0]			

*CLMASK[3:0]: Current Limit MASKing time*CLMASK[3:0]=0h: Mask Time 0.2 μ sCLMASK[1:0]=x: Mask Time $0.2 * (1 + x) \mu$ sCLMASK[3:0]=Fh: Mask Time 3.2 μ s

In order to prevent noise and glitches causing from false current limiting, this mask time can be programmed.

*OCMASK[3:0]: OverCurrent MASKing time*OCMASK[3:0]=0h: Overcurrent mask time 0.2 μ s

OCMASK[3:0]=x:

Overcurrent mask time $0.2 * (1 + x) \mu$ sOCMASK[3:0]=Fh: Overcurrent mask time 3.2 μ s

The time to detect overcurrent can be programmed with OCMASK.

MRCONF4 (Default: 00h)

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0104h	MRCONF4	SROFFT[3:0]				CRMASK[3:0]			

SROFFT[3:0]: Synchronous Rectification OFF Time

A reverse current detection at -25% of CLSEL can disable for a programmable time the synchronous rectification, e.g. to avoid that the power supply is lifted when the motor current is reduced quickly.

SROFFT[3:0]=0h: Synchronous rectification off time 4 FG

SROFFT[3:0]=x:

Synchronous rectification off time $4 * (1 + x)$ FG

SROFFT[3:0]=Fh: Synchronous rectification off time 64 FG

CRMASK[3:0]: Current Reversed MASKing time

This is the masking time of the reverse current detection before triggering SROFFT.

CRMASK[3:0]=0h: Mask time 3.2 μ sCRMASK[3:0]=x: Mask time $0.2 * (16 - x) \mu$ sCRMASK[3:0]=Fh: Mask time 0.2 μ s

MRCONF5 (Default: 00h)

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0105h	MRCONF5	SYNCEN	PPDOSEL	FSCDT[1:0]		FSCDL[3:0]			

SYNCEN: SYNChronous rectification ENable (active low)

SYNCEN=0: Synchronous rectification is ON. (Synchronous rectification mode)

SYNCEN=1: Synchronous rectification is OFF. (Asynchronous rectification mode)

SYNCEN defines synchronous rectification mode for the output stage. In synchronous rectification mode, the high and low-side switches are always switched in complementary mode. In asynchronous rectification mode, both complementary switches may be off and the motor current is circling through the body diodes.

PPDOSEL: Pwm Problem Diagnostics Output SElection

PPDOSEL=0: Abnormal PWM input detected result is reflected to DIAG pin.

PPDOSEL=1: Abnormal PWM input detected result is not reflected to DIAG pin.

FSCDT[1:0]: Fet Short-Circuit Detection Time

FSCDT[1:0]=0h: Detection time 3.2 μ s

FSCDT[1:0]=1h: Detection time 6.4 μ s

FSCDT[1:0]=2h: Detection time 9.6 μ s

FSCDT[1:0]=3h: Detection time 12.8 μ s

By monitoring FET Vds, the time from FET's ON signal output until detecting shorted status can be set with FSCDT.

FSCDL[3:0]: Fet Short-Circuit Detection Level

FSCDL[3:0]=0h: Detection voltage 0.1 V

FSCDL[3:0]=x: Detection voltage 0.1 * (1 + x) V

FSCDL[3:0]=Fh: Detection voltage 1.6 V

MRCONF6 (Default: 00h)

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0106h	MRCONF6	0	CPTM[3:0]				THTH[1:0]		TSTS

CPTM[3:0]: Constrained movement Protection TiMe

CPTM[3:0]=0h: Detection time 0.4 s / Restart time 3.2 s

CPTM[3:0]=x: Detection time 0.4 * (1 + x) s / Restart time 0.4 * 8 * (1 + x) s

CPTM[3:0]=Fh: Detection time 6.4 s / Restart time 51.2 s

A locked rotor protection circuit is embedded in order to protect IC and Motor during locked rotor conditions. A locked rotor is detected by counting the time the IC is in Startup mode (without BEMF detection). If no BEMF is detected for the time programmed into CPTM register, the motor is turned off and a locked rotor is flagged.

In auto-recovery mode, the motor will remain off for eight times the Open-Loop Startup Timeout before another startup is attempted.

THTH[1:0]: THreshold of THermometer

THTH[1:0]=0h: Detection voltage 0.35 V

THTH[1:0]=1h: Detection voltage 0.30 V

THTH[1:0]=2h: Detection voltage 0.25 V

THTH[1:0]=3h: Detection voltage 0.20 V

LV8961H has an embedded comparator to monitor the external power FET temperature via an external thermistor. If the voltage at TH exceeds the threshold shown in the table, the power stage is shut off and a THPO error is triggered.

TSTS: Thermal Shutdown Temperature Setting

TSTS=0: Overtemperature warning occurs at 125°C(typ), shutdown at 150°C (typ).

TSTS=1: Overtemperature warning occurs at 150°C (typ), shutdown at 175°C (typ).

The LV8961H monitors its own junction temperature to protect against overtemperature damage. Two different warning- and shutoff levels can be selected.

MRCONF7 (Default: 00h)

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0107h	MRCONF7	WDTEN	WDTSEL[2]	WDT[5:0]					

WDTEN: WatchDog Timeout Enable

WDTEN=0: Watchdog is disabled.

WDTEN=1: Watchdog is active.

This bit can enable or disable the watchdog.

WDTSEL[2:0]: WatchDog Target duty SElection

1bit [2] of WDTSEL[2:0] register

WDTSEL[2:0]=0h,7h: Motor duty cycle 0%

WDTSEL[2:0]=1h: Motor duty cycle 25%

WDTSEL[2:0]=2h: Motor duty cycle 50%

WDTSEL[2:0]=3h: Motor duty cycle 75%

WDTSEL[2:0]=4h: Motor duty cycle 100%

WDTSEL[2:0]=5h: Motor duty cycle is indicated by TAG_L

WDTSEL[2:0]=6h: Motor duty cycle is indicated by TAG_H

If this register is set, a watchdog timeout causes Halt mode (0% drive) or Drive mode. When Drive mode is selected, the motor duty cycle is defined by this register and TAG_L, TAG_H registers.

WDT[5:0]: WatchDog Timeout duration setting

WDT[5:0]=00h: Detection time 1.6 ms

WDT[5:0]=x: Detection time $1.6 * (1 + x)$ ms

WDT[5:0]=3Fh: Detection time 102.4 ms

Writing 00h to register MRRST(Address = 0300h) resets the watchdog timer. When the watchdog timer reaches its end detection time, a watchdog error is issued.

MRCONF8 (Default: 00h)

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0108h	MRCONF8	VCLVPEN	CPEN	THWEN	THPEN	FSPEN	OVPEN	OCPEN	DIAGSEL

xEN: Error and warning mask

VCLVPEN: VCc Low Voltage Protection ENable.

CPEN: Constrained movement Protection ENable.

THWEN: THERmal Warning ENable.

THPEN: THERmal Protection ENable.

FSPEN: Fet Short Protection ENable

OVPEN: OverVoltage Protection ENable.

OCPEN: OverCurrent Protection ENable.

The higher seven bits in this register allows enabling and disabling of various errors and warnings. Setting xEN=1 masks the error, setting xEN=0 activates the error.

DIAGSEL: DIAG polarity SElection

DIAGSEL=0: The DIAG pin is active low.

DIAGSEL=1: The DIAG pin is active high.

This bit selects the polarity of the DIAG signal.

The DIAG pin is OPEN drain.

MRCONF9 (Default: 00h)

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0109h	MRCONF9	RCVTM[1:0]		WDTSEL[1:0]		CPLT	FSPLT	OCPLT	DLTO

RCVTM[1:0]: ReCoVery TiMe setting

RCVTM[1:0]=0h: Recovery time 0 s

RCVTM[1:0]=1h: Recovery time 5 s

RCVTM[1:0]=2h: Recovery time 10 s

RCVTM[1:0]=3h: Recovery time 20 s

IC will restart (after an abnormal rotational speed change is detected) when this recovery time elapses.

WDTSEL[1:0]: WatchDog Target duty SElection

2bit [1:0] of WDTSEL[2:0] register

See MRCONF7 register.

xPLT: Protection LaTch selection

CPLT=0: Auto recover after constrained movement detection.

CPLT=1: Latch the IC off after constrained movement detection.

FSPLT=0: Auto recover after FET short detection.

FSPLT=1: Latch the IC off after FET short detection.

OCPLT=0: Auto recover after overcurrent detection.

OCPLT=1: Latch the IC off after overcurrent detection.

Motor constraint, FET short, and overcurrent can cause intolerable large-current flow in the application. To prevent repeated current flow during retry attempts, it is possible to latch these errors.

DLTO: Diagnostics output Latched Transitions Only

DLTO=0: Trigger DIAG for any non-masked error or warning.

DLTO=1: Trigger DIAG only for latched errors as defined by above xPLTs.

MRCONF10 (Default: 00h)

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]

VDHOVPEN: VDH OverVoltage Protection ENable.

OOPOEN: Open cOnnector Protection Output ENable.

CLDOEN: Current Limit Detection Output ENable.

The higher three bits in this register allow enabling and disabling of various errors and warnings. Setting xEN=1 masks the error, setting xEN=0 activates the error.

FGERACCEN: FrequenY Generator ERrordetection during ACCEleration ENabled

FGERACCEN=0: FG error detection at acceleration is disabled.

FGERACCEN=1: FG error detection at acceleration is enabled

RCSMPMD: Register CheckSuM error then Power Motor Down

RCSMPMD=0: Keep motor running after checksum error detection.

RCSMPMD=1: Power down motor after checksum error detection.

Register checksum error information is always output to DIAG when RCSMEN register is set, and it is independent of RCSMPMD setting.

RCSMPEN: Register CheckSuM Periodical at running motor ENable

RCSMPEN=0: Register checksum calculation is done at following timing.

- Device startup
- Writing OTP
- OTP download by writing MRODL=00h

RCSMPEN=1: Register checksum calculation is done at following timing.

- Device startup
- Writing OTP
- OTP download by writing MRODL=00h
- 1 ms periodically at motor running

OPDTM[1:0]: OPen connector Detection TiMe selection

OPDTM[1:0]=0h: Detection time 160 μ s

OPDTM[1:0]=1h: Detection time 320 μ s

OPDTM[1:0]=2h: Detection time 640 μ s

OPDTM[1:0]=3h: Detection time 1280 μ s

When the motor cannot be started for a certain period of time and it is in the startup mode, this IC flows current to each coil, then determines IC is in a constraint state when current flows, or an open state when no current flows. The detection time for the current to flow can be selected by OPDTM.

MRCONF11 (Default: 00h)

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
010Bh	MRCONF11	INIODUTYMD	INITAGMD	CLREFEN_ROT	CLREFEN_STOP	ATSYNCOFF	0	STSYNCEN	SPIINSEL

INIODUTYMD: INItial Output DUTY cycle MoDe (soft start function)

INIODUTYMD=0: Input PWM duty

INIODUTYMD=1: Ramp up from 0%

INITAGMD: INItial max. TArGet output duty cycle MoDe

INITAGMD=0: Input PWM duty

INITAGMD=1: PDTSEL setting

CLREFEN_ROT: Current Limit REFErence ENable (free ROTating status)

CLREFEN_ROT=0: Disable current ramp (soft start) in free-run status.

CLREFEN_ROT=1: Enable current ramp (soft start) in free-run status.

CLREFEN_STOP: Current Limit REFErence ENable (STOP status)

CLREFEN_STOP=0: Disable disable current ramp (soft start) in stop status.

CLREFEN_STOP=1: Enable current ramp (soft start) in stop status.

ATSYNCOFF: AuTomatic SYNChronous rectification OFF (active low)

This bit activates the automatic disabling of synchronous rectification.

ATSYNCOFF=0: Automatic synchronous rectification off function is enabled.

ATSYNCOFF=1: Automatic synchronous rectification off function is disabled.

STSYNCEN: SoftStart SYNChronous rectification ENable (active low)

STSYNCEN=0: Synchronous rectification at soft start depends on SYNCEN.

STSYNCEN=1: Synchronous rectification at soft start is forced off.

SPIINSEL: duty cycle through SPI INput SElection

SPIINSEL=0: Input duty from pin. (HVPIN/LVPIN)

SPIINSEL=1: Input duty from PWMDTIN register (concatenation of MRCTL1[1:0] and MRCTL0[7:0]).

MRCONF12 (Default: 00h)

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
010Ch	MRCONF12	FGERDECEN	FGERDEC[2:0]			FGERACC[3:0]			

FGERDECEN: Frequency Generator Error detection during DEceleration ENable

FGERDECEN=0: FG error detection at deceleration is disabled.

FGERDECEN=1: FG error detection at deceleration is enabled

FGERDEC[2:0]: Frequency Generator Error detection during DEceleration setting

FGERDEC[2:0]=0h: Limit of zero-cross detection time is (previous 60 electrical degrees period) * 1.25.

FGERDEC[2:0]=1h: Limit of zero-cross detection time is (previous 60 electrical degrees period) * 1.5.

FGERDEC[2:0]=2h: Limit of zero-cross detection time is (previous 60 electrical degrees period) * 1.75.

FGERDEC[2:0]=3h: Limit of zero-cross detection time is (previous 60 electrical degrees period) * 2.

FGERDEC[2:0]=4h: Limit of zero-cross detection time is (previous 60 electrical degrees period) * 3.

FGERDEC[2:0]=5h: Limit of zero-cross detection time is (previous 60 electrical degrees period) * 4.

FGERDEC[2:0]=6h: Limit of zero-cross detection time is (previous 60 electrical degrees period) * 6.

FGERDEC[2:0]=7h: Limit of zero-cross detection time is (previous 60 electrical degrees period) * 8.

FGERACC[3:0]: Frequency Generator Error detection during ACCeleration setting

FGERACC[3:0]=0h: 1 time detecting zero-cross of BEMF when the moment the Mask signal is opened.

FGERACC[3:0]=x: (1 + x) consecutive time detecting zero-cross of BEMF when the moment the Mask signal is opened.

FGERACC[3:0]=Fh: 16 consecutive time detecting zero-cross of BEMF when the moment the Mask signal is opened.

MRCONF13 (Default: 00h)

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
010Dh	MRCONF13	0	DWNSET	PDTSEL[1:0]		FSPDTM[1:0]		OVPMASK[1:0]	

DWNSET: slowDoWN SETting

DWNSET=0: Normal mode

DWNSET=1: Synchronous rectification OFF mode

During speed control mode, motor deceleration can lead to energy recuperation and temporary voltage spikes. DWNSET allows for various degrees of energy recuperation:

- Normal Mode

Results in a tightest control and maximum energy recuperation. The application circuit has to be able to absorb the energy generated.

- Synchronous rectification OFF Mode

The motor is essentially not driven until it has reached the target speed. This does not feed any energy back into the supply, but may take a long time if motor inertia is high and losses are low.

PDTSEL[1:0]: Pending Detection of a Transition SElection

PDTSEL[1:0]=0h: Motor duty cycle 25%

PDTSEL[1:0]=1h: Motor duty cycle 50%

PDTSEL[1:0]=2h: Motor duty cycle 75%

PDTSEL[1:0]=3h: Motor duty cycle 100%

If PDTC is set, the motor is driven with the duty cycle programmed into PDTSEL, as soon as EN is high.

This feature is bridging the initial 200 ms of operation until a valid PWM duty cycle can be decoded.

FSPDTM[1:0]: Fet Short Protection Debounce Time setting

FSPDTM[1:0]=0h: Debounce time 1.6 μ s

FSPDTM[1:0]=1h: Debounce time 3.2 μ s

FSPDTM[1:0]=2h: Debounce time 4.8 μ s

FSPDTM[1:0]=3h: Debounce time 6.4 μ s

OVPMASK[1:0]: OverVoltage Protection MASKing time

The time to detect overvoltage condition on VS and VDH can be set by OVPMASK.

OVPMASK[1:0]=0h: Detection time 0.8 μ s

OVPMASK[1:0]=1h: Detection time 1.6 μ s

OVPMASK[1:0]=2h: Detection time 3.2 μ s

OVPMASK[1:0]=3h: Detection time 6.4 μ s

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0200h	MRACS	0	0	0	0	0	RCSMEN	OSAENB	MSAENB

This data, which is a read-only register, is downloaded from OTP memory ORCONF33.

RCSMEN: Register CheckSum ENable

RCSMEN=0: Register checksum diagnostic function is disabled.

RCSMEN=1: Register checksum diagnostic function is enabled

OSAENB: Otp registers Spi Access ENable Bar (Disable)

OSAENB=0: Write access permitted.

OSAENB=1: Write access denied.

OSAENB controls write access to the OTP registers.

MSAENB: Main registers Spi Access ENable Bar (Disable)

MSAENB=0: Write access permitted.

MSAENB=1: Write access denied.

MSAENB controls write access to the main registers.

MRDIAG0

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0201h	MRDIAG0	CPO	THPO	FSPO	VGLLVPO	CHPLVPO	VSOVPO	VSLVPO	OCPO

CPO: Constrained movement Protection Output

CPO=0: Normal

CPO=1: Detect locked rotor error

No BEMF was detected during the entire open-loop startup time as programmed in CPTM. Either the rotor is blocked, or startup parameters are not correct. The drivers are disabled.

THPO: fet Thermal Protection Output

THPO=0: Normal

THPO=1: Detect FET thermal error

FSPO: Fet Short Protection Output

FSPO=0: Normal

FSPO=1: Detect FET short error

The drain–source voltage threshold across one of the external power FETs has been exceeded during operation. The threshold voltage is programmed in register FSCDL. Errors are suppressed for a blanking time as programmed in register FSCDT, both in register MRCONF5.

For the high–side FETs this voltage is measured between pin VS and the corresponding phase connection UOUT, VOUT, WOUT. For the low–side FETs it is measured between the phase connection and the pins SUL, SVL and SWL. Make sure to minimize potential voltage drops in the sense paths.

VGLLVPO: VGL Low Voltage Protection Output

VGLLVPO=0: Normal

VGLLVPO=1: Detect VGL undervoltage error

The voltage at VGL has dropped below 5.5 V (max). The drivers are disabled to protect against low gate enhancement.

CHPLVPO: CHarge Pump Low Voltage Protection Output

CHPLVPO=0: Normal

CHPLVPO=1: Detect CHP low voltage error

The voltage between VS and VCP has dropped below 5.5 V (max). The drivers are disabled to protect against low gate enhancement.

VSOVPO: VS OverVoltage Protection Output

VSOVPO=0: Normal

VSOVPO=1: Detect VS over voltage error

The voltage at VS has exceeded 28 V (min). The driver stage and the charge pump are disabled to protect against overvoltage at the charge pump.

VSLVPO: VS Low Voltage Protection Output

VSLVPO=0: Normal

VSLVPO=1: Detect VS undervoltage error

The voltage at VS has fallen below 5.1 V (max). The driver stage is disabled to protect against internal threshold issues.

OCPO: OverCurrent Protection Output

OCPO=0: Normal

OCPO=1: Detect overcurrent error

The voltage between current sense pins RFSENS and RF has exceeded overcurrent threshold voltage for longer than the overcurrent limit mask time programmed in register OCMASK in MRCONF3. The driver stage is disabled to protect against damage.

MRDIAG1

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0202h	MRDIAG1	PWMPO	VCLVPO	RCSMPO	OOPO	CLDO	WDTPO	THSPO	THWPO

PWMPO: PWM input abnormal Protection Output

PWMPO=0: Normal

PWMPO=1: Detect PWM input error

The PWM input does not oscillate with the appropriate frequency or is steady high (100%) or low (0%). Depending on the settings FLSEL, ZPSEL in MRCONF1, the driver stage will turn off, or operate at a predefined duty cycle (emergency mode).

VCLVPO: VCc Low Voltage Protection Output

VCLVPO=0: Normal

VCLVPO=1: Detect VCC undervoltage error

VCC undervoltage error. Depending on the setting of REGSEL in MRCONF0, VCC is either 5 V (typ) or 3.3 V (typ). Undervoltage is flagged if VCC falls below 4.2 V (max) or 2.7 V (max) respectively.

RCSMPO: Register CheckSum Protection Output

RCSMPO=0: Normal

RCSMPO=1: Detect register checksum error

RCSMPO is set when EN=1, RCSMEN=1, RCSMPEN=1 and register checksum error is detected. If RCSMPMD is set, the driver stage will be off.

RCSMPO is cleared by writing 55h to register MRRST.

OOPO: Open cOnnector Protection Output

OOPO=0: Normal

OOPO=1: Detect open connector

CLDO: Current Limit Detection Output

CLDO=0: Normal

CLDO=1: Detect current limitation

WDTPO: WatchDog Timer Protection Output

WDTPO=0: Normal

WDTPO=1: Detect WDT error

The watchdog has timed out. This flag will be high if the watchdog was not reset during the time defined by register WDT in MRCONF7. If the watchdog is enabled the driver stage will either be off or run in emergency mode with the settings defined by register WDTSEL in MRCONF7, MRCONF9.

Flag WDTPO is high even if the watchdog is disabled.

THSPO: Thermal Shutdown Protection Output

THSPO=0: Normal

THSPO=1: Detect thermal shutdown error

The IC temperature is too high and the drivers are shut off. The overtemperature shutoff level is defined by TSTS in MRCONF6 to be either 150°C (min.) or 175°C (min.).

THWPO: Thermal Warning Protection Output

THWPO=0: Normal

THWPO=1: Detect thermal warning error

The IC temperature has exceeded the warning level. The overtemperature warning level is defined by TSTS in MRCONF6 to be either 125°C (min.) or 150°C (min.).

MRDIAG2

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0203h	MRDIAG2	0	0	OTPAZ	REGAZ	FGERPO	SPCO	STUPO	VDHOVPO

OTPAZ: OTP All bits Zero

OTPAZ=0: OTP contains at least one zapped bit.

OTPAZ=1: Detect that OTP output is all 0.

REGAZ: otp REGISTER All bits Zero

REGAZ=0: Registers which data is downloaded from OTP contains at least 1-bit one.

REGAZ=1: Detect that registers which data is downloaded from OTP is all 0.

FGERPO: Frequency Generator ERROR Protection Output

FGERPO=0: The absolute value of the speed error is not detected under FGERACC/FGERRDEC conditions.

FGERPO=1: The absolute value of the speed error is detected under FGERACC/FGERRDEC conditions.

SPCO: Speed Control error Output

SPCO=0: The absolute value of the speed error is equal to or less than target * 1/16.

SPCO=1: The absolute value of the speed error is greater than target * 1/16.

STUPO: bEMF-less STARTUp Period Output

STUPO=0: BEMF has been detected.

STUPO=1: No BEMF has been detected, yet.

This flag indicates open-loop startup operation.

VDHOVPO: VDH OverVoltage Protection Output

VDHOVPO=0: Normal

VDHOVPO=1: Detect VDH over voltage error

MRDIAG3

BRK: short BRaKe enable

BRK=0: Short brake is disabled.

BRK=1: Short brake is enabled.

Note that when short brake is executed, an overcurrent flows due to the electromotive force generated when the motor rotates.

PWMDTIN[9:0]: PWM DuTy cycle INput register

PWMDTIN[9:0]=000h: Duty cycle

0% to 0.098%

PWMDTIN[9:0]=x: Duty cycle

$(x * 100 / 1024) \%$ to $((x+1) * 100 / 1024) \%$

PWMDTIN[9:0]=3FFh: Duty cycle

99.9% to 100%

MRCTL5 (Default: 00h)

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
0306h	MRCTL5	0	0	0	0	STATSEL[3:0]			

STATSEL[3:0]: STATus data SElection

STATSEL selects status data output to STATUS[23:0] (concatenation of MRSTAT2[7:0], MRSTAT1[7:0] and MRSTAT0[7:0]).

STATUS[23:8] are latched when STATUS[7:0] is read.

If STATSEL is changed before reading STATUS[23:8], they hold value which is indicated by previous STATSEL until STATUS[7:0] will be read.

If STATUS[23:8] is read soon after reset, they returns 0000h.

STATUS Register Description

Users can know various operation status, such as rotation period/frequency, input duty cycle, PWM output period, lead angle control etc. by reading out the register STATUS[23:0] which is divided into three bytes and stored in the address 0205h to 0207h. The register STATSEL[3:0] stored in the address 0306h determines which status

parameter is allocated to the STATUS register. When read access to the address 0205h (first byte of STATUS [23:0]) was initiated, the register data in the following address 0206h and 0207h will not change during the sequential read access to these addresses so that the simultaneity of three bytes which form STATSEL[23:0] is secured.

ORBLV=1: OTP high bias read mode (high level margin check) at ORBEN=1

This register modifies the OTP readout threshold. After programming the OTP registers should be verified by reading them with the readout thresholds set low and high to detect false zeros and ones

OTP Register

The OTP Registers contain the default values of the system registers. These registers are always readable via SPI in either Standby or Normal modes. During device startup these default values are copied from the OTP bank (SPI addresses 1000h to 1022h) to the main register bank (SPI addresses 0000h to 0401h). The OTP registers should only be programmed once during IC initialization, during normal operation only the main registers are accessed and modified. It is possible to block programming of the OTP section by setting the OSAENB bit in the ORCONF33 Register of the OTP. For detailed information on the content of the OTP, see the corresponding main register descriptions in the previous section.

ORCONF0 – ORCONF4 (assigned to OTP bank 0)

1022h	ORCONF34	RCSM[7:0]							

OTP write is start when ORCONF34 is written.

ORCONF33[7:4] has no register to download, but OTP output is used for checksum calculation.

OTP Data Download

The OTP register data is typically transferred into the main registers at device startup (From sleep to standby transition). This operation takes up to 340 μ s. A high OBSY flag in the first returned byte during a SPI transaction indicates this.

Figure 22. OTP Data Download Timing at Startup

An OTP download can also actively be initiated by writing 00h to register MRODL. This command requires monitoring the OBSY flag. Don't perform specific register access (MRCONF, MRSPCT, ORCONF) until the OBSY flag is cleared.

Figure 23. OTP Data Download Timing after an MRODL Command

OTP Programming Overall

Figure 24 shows overall of the OTP memory write and verify flow. It consists of preparation, write and three times of data integrity verification.

OTP Programming

The OTP registers can be programmed in Standby mode only while the write lock bit OSAENB is set 0. And, the supply voltage at pin VS must be more than 1.4 V. The actual write operation to the OTP memory will be done, when the state change from 0 to 1 is commanded. Once the bit state is changed to 1, it cannot be change back to 0. The number of writing is limited to one per bit.

The OTP memory consists of five memory banks. The bank contains five register bytes. The bank is filled by five SPI write transactions. When the last address register in each bank is received, the busy-flag OBSY will be set and those five bytes will be programmed permanently into the corresponding OTP bank. The OBSY flag will be reset at the end of the write cycle. OBSY is in GSDAT register. To get GSDAT, SPI accesses to the register MRACK is recommended. MRACK doesn't interfere with the programming operation. MRCONF, MRSPCT, ORCONF registers cannot be accessed during an OTP write cycle.

MRCONF, MRSPCT, ORCONF, ORSPCT, ORACS registers cannot be accessed during an OTP write cycle.

Figure 24. OTP Memory Write and Verify Flow

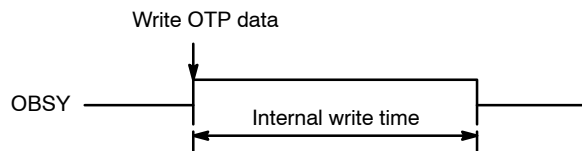

Figure 25. OTP Programming Timing

The programming takes 20 ms maximum. To simplify operation, a waiting for 20 ms plus margin can be applicable instead of a polling of the flag OBSY. (Figure 26)

Figure 26. OTP Memory Write Operation

OTP Data Integrity Verification

In order to verify that the OTP programming operation was successful. It is strongly recommended to do an OTP margin check: To do this, the OTP registers are downloaded into the main register bank with minimum and maximum readout thresholds. This OTP download is forced by writing 00h to register MRODL. The readout threshold is set in register MRORB.

OTP Margin read check sequence after programmed:

1. Set OTP readout threshold “low” by setting ORBEN = 1 and ORBLV = 0 in register MRORB
2. Execute OTP download command by writing 00h to MRODL
3. Verify that the main register contents are consistent with the programmed OTP data
4. Set OTP readout threshold “high” by setting ORBEN = 1 and ORBLV = 1 in register MRORB
5. Execute OTP download command by writing 00h to MRODL

6. Verify that the main register contents are consistent with the programmed OTP data
7. Return OTP threshold to normal by setting ORBEN = 0 and ORBLV = 0
8. Execute OTP download command
9. Verify that the main register contents are consistent with the programmed OTP data

Locking OTP Register Contents

MSAENB bit and OSAENB bit of ORCONF33 register are used in order to prevent write-access of the main registers and the OTP registers respectively.

CAUTION: Inadvertent writing of these bits will permanently lock the corresponding register blocks from any further write access. Should only be set at end of development cycles.

ORCONF33

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
1021h	ORCONF33	0	0	0	0	RBSEL	RCSMEN	OSAENB	MSAENB

RBSEL: Reverse detection Brake SElection

RBSEL=0: Short brake is disabled when reverse rotation is detected.

RBSEL=1: Short brake is enabled when reverse rotation is detected.

If RBSEL is set, short brake (all low-side FET are ON) is done until the rotation stops after reverse rotation is detected.

RCSMEN: Register CheckSum ENable

RCSMEN=0: Register checksum diagnostic function is disabled.

RCSMEN=1: Register checksum diagnostic function is enabled.

This register is used in order to permanently prevent write access to the OTP and/or the main registers. This register data is transferred into MRACS register.

OSAENB: Otp registers Spi Access ENable Bar (Disable)

- OSAENB = 0: Write access permitted
- OSAENB = 1: Write access denied

OSAENB controls write access to the OTP registers.

MSAENB: Main registers Spi Access ENable Bar (Disable)

- MSAENB = 0: Write access permitted
- MSAENB = 1: Write access denied

MSAENB controls write access to the main registers.

ORCONF34

ADDR	Data Name	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]
1022h	ORCONF34	RCSM[7:0]							

RCSM: Register CheckSum

The checksum of whole OTP memory data except this register ORCONF34 needs to be written when the data integrity diagnostic function is enabled. This checksum is a cyclic redundancy check (CRC) which is calculated by the following generator polynomial.

$$x^8 + x^6 + x^3 + x^2 + 1$$

The read out value of the register RCSMSD must be applied to the CRC calculation as a seed. An example CRC calculation program in C language is shown below.

```
// x8 + x6 + x3 + x2 + 1
#define MSB_CRC8      (0x4D)

unsigned char crc_table[256];
unsigned char crc_seed;

static unsigned char GetCRC8_2( unsigned char seed, const void *buff, size_t size )
{
    unsigned char *p = (unsigned char *)buff;
    unsigned char crc8;
    int i;

    for ( crc8 = seed ; size != 0 ; size-- ){
        crc8 ^= *p++;

        for ( i = 0 ; i < CHAR_BIT ; i++ ){
            if ( crc8 & 0x80 ){
                crc8 <<= 1; crc8 ^= MSB_CRC8;
            }
            else{
                crc8 <<= 1;
            }
        }
    }
    return crc8;
}
```

This program is used in the following procedure.

1. Set ORCONF0 through 33 to crc_table
2. Set CRC code read from the register RCSMSD to crc_seed
3. Call GetCRC8_2(crc_seed, crc_table, 34)
4. Use return value for ORCONF34

Register Checksum Feature

To activate the register checksum feature, the following register bits must be provided before OTP programming operation.

1. Determine the periodical checksum verify function to be enabled or not, which is specified by the bit RCSMPEN

2. Determine the operation at the checksum error detection: A motor is kept running or stopped, which is specified by the bit RCSMPMD
3. The bit RCSMEN must be set 1 to enable this feature
4. Read out the checksum code (CRC) of the OTP memory reserved area from the register RCSMSD[7:0] whose value may be different by part
5. Letting the RCSMSD be a seed for the CRC calculation, prepare the total checksum (CRC) from ORCON0 to ORCON33, which will be used for the register RCSM[7:0] at ORCONF34

The following table shows related register bits to this checksum feature.

Table 14.

Register Name	Data Name	Address	Description
RCSMPEN	ORCONF10	100Ah	Enable the periodical checksum verification while a motor is running
RCSMPMD	ORCONF10	100Ah	Selection of motor running or stop when the checksum error is detected
RCSMEN	ORCON33	1021h	Enable the register checksum function
RCSM	ORCONF34	1022h	Checksum to be written with OTP memory data together, which must be calculated by user, applying the code of RCSMSD as a seed of CRC
RCSMSD	MRCMSD	0208h	Seed of the register checksum
RCSM	MRCONF14	010Eh	Calculated checksum which is automatically calculated on this device Code of this register will be compared with the preprogrammed checksum code in the register RCSM at ORCONF34 OTP memory.
RCSMPO	MRDIAG1	0202h	Checksum error flag
RCSMPEN	MRCONF10	010Ah	Enable the periodical checksum verification while a motor is running. This value will be copied from OTP memory at the device reset or the download operation.
RCSMPMD	MRCONF10	010Ah	Selection of motor running or stop when the checksum error is detected This value will be copied from OTP memory at the device reset or the download operation.

Table 15.

Symbol	Symbol Name Explanation
ATSYNCOFF	AuTomatic SYNChronous rectification OFF (active low)
BAREG	Base Address REGister (short format access)
BASEL	Base Address SElection
BEMFEN	BEMF detection ENabled
BRK	short BRaKe enable
CHPLVPO	CHarge Pump Low Voltage Protection Output
CHPOVPO	CHarge Pump OverVoltage Protection Output
CLDO	Current Limit Detection Output
CLDOEN	Current Limit Detection Output ENable
CLDWNOFF	Current Limit semi-powerDoWN OFF
CLMASK	Current Limit MASKing time
CLMSPD	Current LiMit Semi-PowerDown level
CLREFEN_ROT	Current Limit REFerence ENable (free ROTating status)
CLREFEN_STOP	Current Limit REFerence ENable (STOP status)
CLSEL	Current Limit threshold SElection
CPEN	Constrained movement Protection ENable
CPLT	Constrained movement Protection LaTch selection
CPO	Constrained movement Protection Output
CPTM	Constrained movement Protection TiMe
CRDTO	Current Reversed Detection Output
CRMASK	Current Reversed MASKing time
DDUTYSEL	Detection level of DUTY output changes SElection

Table 15. (continued)

Symbol	Symbol Name Explanation
DIAGS	DIAG Status
DIAGSEL	DIAG polarity SElection
DLTO	Diagnostics output Latched Transitions Only
DSTEPSEL	DownSpeed Transition stEP SElection
DUTY_H	input pwm DUTY cycle High limit
DUTY_L	input pwm DUTY cycle Low limit
DWNSET	slowDoWN SETting
FDTI	Fet Dead Time
FGERACC	Frequeny Generator ERrordetection during ACCeleration setting
FGERACCEN	Frequeny Generator ERrordetection during ACCeleration ENable
FGERDEC	Frequeny Generator ERrordetection during DECeleration setting
FGERDECEN	Frequeny Generator ERrordetection during DECeleration ENable
FGERPO	Frequency Generator ERror Protection Output
FGOF	Frequency Generator Output Frequency (= rotation speed)
FGSTBLMD	Frequency Generator STaBLe MoDe
FLSEL	Full Load fallback level SElection (PWM input 100% duty mode)
FRMD	Forward/Reverse MoDe
FRREN	FRee Running ENable
FSCDL	Fet Short-Circuit Detection Level
FSCDT	Fet Short-Circuit Detection Time
FSPDTM	Fet Short Protection Debounce TiMe setting
FSPEN	Fet Short Protection ENable
FSPLT	Fet Short Protection LaTch selection
FSPO	Fet Short Protection Output
GSDAT	General Status DATa
HIZON	Hlgh Z state ON (active)
IDUTY_IDUTY	Input DUTYcycle
IG	Integral Gain
INIODUTYMD	INItial Output DUTY cycle MoDe (soft start function)
INITAGMD	INItial max. TArGet output duty cycle MoDe
IX	Integral gain eXponent
LACTL_EPOS	Lead Angle ConTrOL Energizing POSition
LANUM0	Lead Angle Number 0 (output monitor)
LANUM1	Lead Angle Number 1 (control input)
LASET_H	Lead Angle SETting at High output duty cycle (100%)
LASET_L	Lead Angle SETting at Low output duty cycle (0%)
LASET_LIM	Lead Angle SETting max. LIMit
LATCH	LATCHed shutdown status
MRACK	Main Register Access Check
MRACS	Main Register ACcess Setting
MRCONF	Main Register CONFIguration
MRDIAG	Main Register DIAGnostics

Table 15. (continued)

Symbol	Symbol Name Explanation
MRODL	Main Register Otp DownLoad
MRORB	Main Register Otp Read Bias check
MRRST	Main Register ReSeT
MRSPCT	Main Register SPeed ConTrol
MSAENB	Main registers Spi Access ENable Bar (Disable)
MSKRSTNUM0_INI	same for startup 6–window mode
MSKRSTNUM0_ONE	MaSK Rate SeTting for bemf observation NUMber 0, for 1–window mode
MSKRSTNUM0_SIX	same for 6–window mode
MSKRSTNUM0_THR	same for 3–window mode
MSKRSTNUM0_TWO	same for 2–window mode
MSKRSTNUM1_INI	same for startup 6–window mode
MSKRSTNUM1_ONE	MaSK Rate SeTting for bemf observation NUMber 1, for 1–window mode
MSKRSTNUM1_SIX	same for 6–window mode
MSKRSTNUM1_THR	same for 3–window mode
MSKRSTNUM1_TWO	same for 2–window mode
NO_OPEN	NO OPEN phases detected
OBSY	Otp BuSY
OCMASK	OverCurrent MASKing time
OCPEN	OverCurrent Protection ENable
OCPLT	OverCurrent Protection LaTch selection
OCPO	OverCurrent Protection Output
OCSEL	OverCurrent threshold SElection
ODL	Otp DownLoad and checksum
ODUTYMAX	Output DUTYcycle MAXimum
OOPO	Open cOnnector Protection Output
OOPOEN	Open cOnnector Protection Output ENable
OPDTM	OPen connector Detection TiMe selection
OPEN_U	OPEN U phase (active low)
OPEN_V	OPEN V phase (active low)
OPEN_W	OPEN W phase (active low)
OPENLX0	OPEN Loop condition for tag0 (active low)
ORBEN	Otp Read Bias check ENable
ORBLV	Otp Read Bias check LeVel
OSAENB	Otp registers Spi Access ENable Bar (Disable)
OTPAZ	OTP All bits Zero
OVPEN	OverVoltage Protection ENable
OVPMASK	OverVoltage Protection MASKing time
PDTC	Pending Detection of a Transition Control
PDTSEL	Pending Detection of a Transition SElection
PG	Proportional Gain
PIDOLT	PI calculated Duty cycle Output resuLT
PPDOSEL	Pwm Problem Diagnostics Output SElection

Table 15. (continued)

Symbol	Symbol Name Explanation
PROT_F	Period of ROTation (Frequency)
PROT_T	Period of ROTation (Time)
PWMDTIN	PWM DuTycycle INput register
PWMF	PWM input Frequency selection
PWMHCNT_LT	PWM input High CouNT (LaTched)
PWMINSEL	PWM INput pin SElection
PWMON	PWM ON polarity
PWMPCNT_LT	PWM input Period CouNT (LaTched)
PWMPO	PWM input abnormal Protection Output
PX	Proportional gain eXponent
RBSEL	Reverse detection Brake SElection
RCSM	Register CheckSuM
RCSMEN	Register CheckSuM ENable
RCSMPEN	Register CheckSuM Periodical at running motor ENable
RCSMPMD	Register CheckSuM error then Power Motor Down
RCSMPO	Register CheckSuM Protection Output
RCSMSD	Register CheckSuM SeeD
RCVTM	ReCoVery TiMe setting
RECALC	RECALCulate target speed from input pwm control table
REGAZ	otp REGister All bits Zero
REGCRC_RSLT	REGister CRC ReSuLT
REGSEL	Vcc REGulator SElection
SACF	Spi ACcess Failed
SCEN	external Speed Control ENable
SLMD	SinusoidaL Mode Driving
SMOD	Status MODe
SPCFG	Speed feedback loop calculation Period ConFiGuration
SPCO	SPeed Control error Output
SPIINSEL	duty cycle through SPI INput SElection
SROFFT	Synchronous Rectification OFF Time
SSCGCN	Spread Spectrum Charge pump Generation Clock Number
SSCGEN	Spread Spectrum Charge pump Generation ENable
SSTT	Soft STart Time
STATSEL	STATus data SElection
STATUS	internal STATUS output
STOSC	STartup OSCillator
STSYNCEN	sofSTart SYNChronous rectification ENable (active low)
STUPO	bemf-less STartUp Period Output
SYNCEN	SYNChronous rectification ENable (active low)
TAG_H	TArGet speed High
TAG_L	TArGet speed Low
TAG0	TArGet speed/output duty cycle 0 (output monitor)

Table 15. (continued)

Symbol	Symbol Name Explanation
TAG1	TArGet speed/output duty cycle 1 (control input)
THPEN	THeRmal Protection ENable
THPO	fet THeRmal Protection Output
THSPO	THeRmal Shutdown Protection Output
THTH	THeRmal Threshold of THeRmometer
THWEN	THeRmal Warning ENable
THWPO	THeRmal Warning Protection Output
TSTS	THeRmal Shutdown Temperature Setting
USTEPSEL	UpSpeed Transition stEP SElection
VCEN	VCc Regulator ENable
VCLVPEN	VCc Low Voltage Protection ENable
VCLVPO	VCc Low Voltage Protection Output
VDHOVPEN	VDH OverVoltage Protection ENable
VDHOVPO	VDH OverVoltage Protection Output
VGLLVPO	VGL Low Voltage Protection Output
VSLVPO	VS Low Voltage Protection Output
VSOVPO	VS OverVoltage Protection Output
WDT	WatchDog Timeout duration setting
WDTEN	WatchDog Timeout Enable
WDTP	WatchDog Timeout Protection mode selection
WDTPO	WatchDog Timer Protection Output
WDTSEL	WatchDog Target-duty SElection
WNDCHNG_EN	WiNDoW mode CHaNGe ENabled
WINDSEL	bemf WiNDoW mode SElection
ZPSEL	Zero Power fallback level SElection (PWM input 0% duty mode)
