

TSOT26 LIGHT LOAD IMPROVED 1.5A SYNCH DC-DC BUCK CONVERTER

Description

The AP65111 is an internally compensated synchronous DC-DC buck converter with a 500kHz switching frequency. It is integrated with high and low-side MOSFETs with low $R_{DS(ON)}$.

The AP65111 enables continuous load current of up to 1.5A with efficiency as high as 97%.

The AP65111 implements an automatic custom light-load efficiency improvement algorithm.

The AP65111 features current mode control operation, which enables fast transient response times and easy loop stabilization.

The AP65111 simplifies board layout and reduces space requirements with its high level of integration and minimal need for external components, making it ideal for distributed power architectures.

The AP65111 is available in a standard Green TSOT26 package and is RoHS compliant.

Pin Assignments

Features

- V_{IN} 4.5V to 16V
- 1.5A Continuous Output Current
- Efficiency Up to 97%
- Automated Light-Load improvement
- V_{OUT} Adjustable from 0.8V
- 500kHz Switching Frequency
- Internal Soft-Start
- Enable Pin
- Overvoltage Protection & Undervoltage Protection
- Overcurrent Protection (OCP) with Hiccup
- Thermal Protection
- **Totally Lead-Free & Fully RoHS Compliant (Notes 1 & 2)**
- **Halogen and Antimony Free. "Green" Device (Note 3)**

Applications

- Gaming Consoles
- Flat-Screen TV Sets and Monitors
- Set-Top-Boxes
- Distributed Power Systems
- Home Audio
- Consumer Electronics
- Network Systems
- FPGA, DSP and ASIC Supplies
- Green Electronics

Notes: 1. No purposely added lead. Fully EU Directive 2002/95/EC (RoHS) & 2011/65/EU (RoHS 2) compliant.
 2. See http://www.diodes.com/quality/lead_free.html for more information about Diodes Incorporated's definitions of Halogen- and Antimony-free, "Green" and Lead-free.
 3. Halogen- and Antimony-free "Green" products are defined as those which contain <900ppm bromine, <900ppm chlorine (<1500ppm total Br + Cl) and <1000ppm antimony compounds.

Typical Applications Circuit

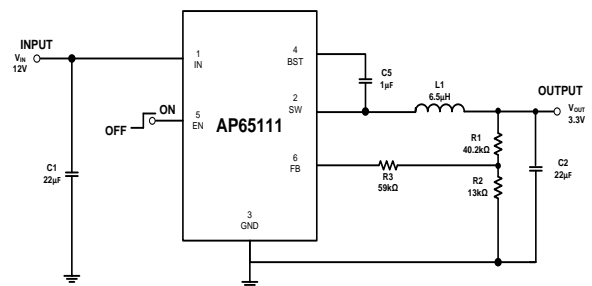

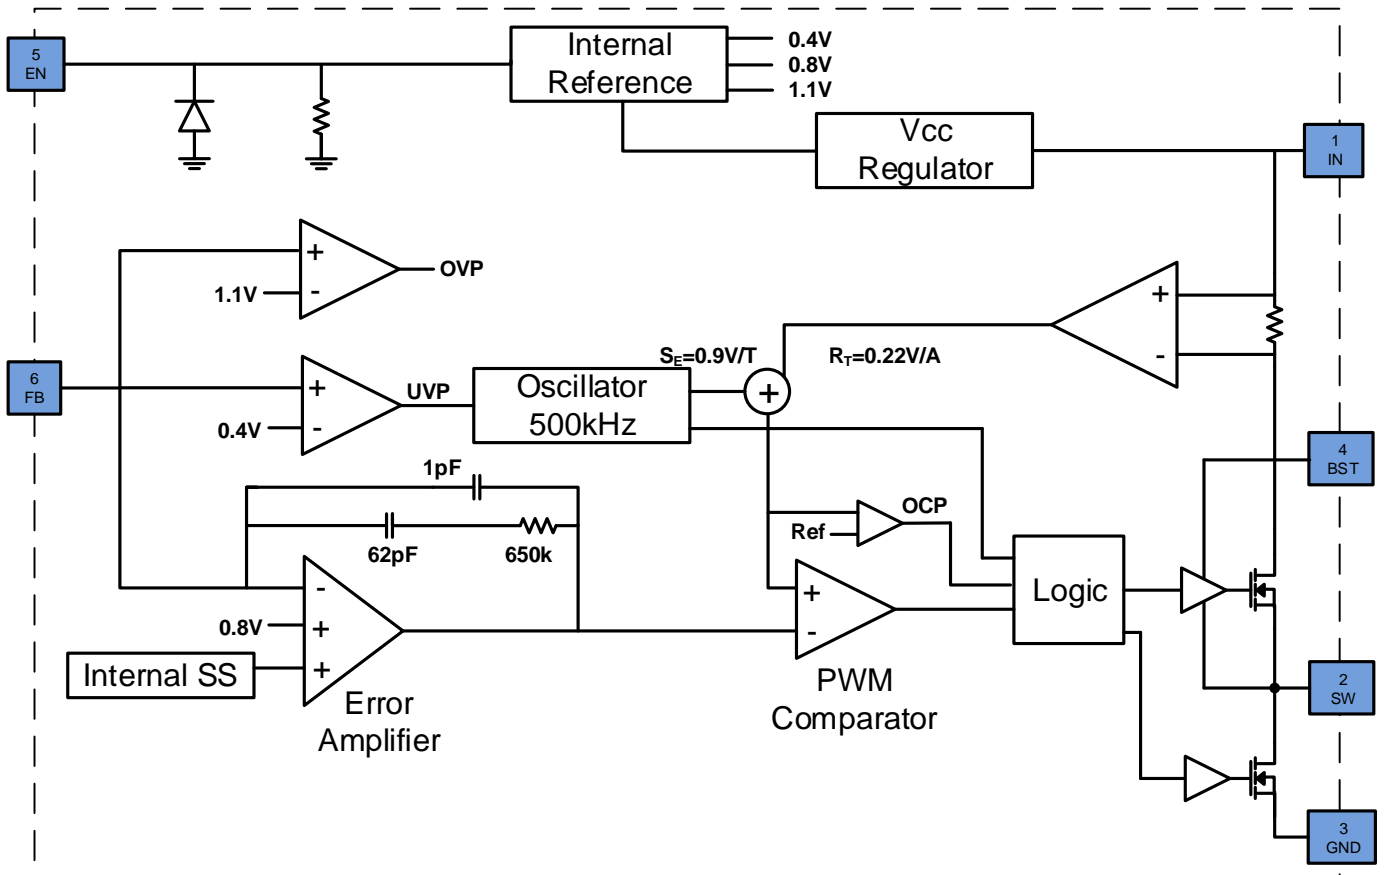

Figure 1 Typical Application Circuit

Pin Descriptions

Pin Name	Pin Number	Function
	TSOT26	
IN	1	Power Input. IN supplies the power to the IC, as well as the step-down converter switches. Drive IN with a 4.5V to 16V power source. Bypass IN to GND with a suitably large capacitor to eliminate noise on the input to the IC. See Input Capacitor on Page 10.
SW	2	Power Switching Output. SW is the switching node that supplies power to the output. Connect the output LC filter from SW to the output load. Note that a capacitor is required from SW to BS to power the high-side switch.
GND	3	Ground
BST	4	High-Side Gate Drive Boost Input. BS supplies the drive for the high-side N-Channel MOSFET a 0.01μF or greater capacitor from SW to BS to power the high-side switch.
EN	5	Enable Input. EN is a digital input that turns the regulator on or off. Drive EN high to turn on the regulator; low to turn it off. Attach to IN with a 100kΩ pull up resistor for automatic startup.
FB	6	Feedback Input. FB senses the output voltage and regulates it. Drive FB with a resistive voltage divider connected to it from the output voltage. The feedback threshold is 0.8V. See Setting the Output Voltage on Page 9.

Functional Block Diagram

Absolute Maximum Ratings (@T_A = +25°C, unless otherwise specified.) (Note 4)

Symbol	Parameter	Rating	Unit
V _{IN}	Supply Voltage	-0.3 to 20	V
V _{SW}	Switch Node Voltage	-1.0 to V _{IN} +0.3	V
V _{BS}	Bootstrap Voltage	V _{SW} -0.3 to V _{SW} +6.0	V
V _{FB}	Feedback Voltage	-0.3V to +6.0	V
V _{EN}	Enable/UVLO Voltage	-0.3V to +6.0	V
T _{ST}	Storage Temperature	-65 to +150	°C
T _J	Junction Temperature	+160	°C
T _L	Lead Temperature	+260	°C
ESD Susceptibility (Note 5)			
HBM	Human Body Model	2	kV
CDM	Charged Device Model	1	kV

- Notes:
- Stresses greater than the 'Absolute Maximum Ratings' specified above may cause permanent damage to the device. These are stress ratings only; functional operation of the device at these or any other conditions exceeding those indicated in this specification is not implied. Device reliability may be affected by exposure to absolute maximum rating conditions for extended periods of time.
 - Semiconductor devices are ESD sensitive and may be damaged by exposure to ESD events. Suitable ESD precautions should be taken when handling and transporting these devices.

Thermal Resistance (Note 6)

Symbol	Parameter	Rating		Unit
θ _{JA}	Junction to Ambient	TSOT26	120	°C/W
θ _{JC}	Junction to Case	TSOT26	30	°C/W

- Note: 6. Device mounted on FR-4 substrate, single-layer PC board, 2oz copper, with minimum recommended pad layout.

Recommended Operating Conditions (@T_A = +25°C, unless otherwise specified.) (Note 7)

Symbol	Parameter	Min	Max	Unit

Application Information

Theory of Operation

The AP65111 is a 1.5A current mode control, synchronous buck regulator with integrated power MOSFETs. Current mode control assures excellent line regulation, load regulation, and a wide loop bandwidth for fast response to load transients. See Figure 1 for the functional block diagram of AP65111.

The operation of one switching cycle consists of the rising edge of the 500kHz oscillator clock signal setting the RS Flip-Flop. Its output turns on the HS MOSFET, upon which the inductor current will start to increase. The current sense amplifier senses and amplifies the inductor current with a gain of 0.22V/A. Since the current mode control is subject to sub-harmonic oscillations that start at half of the switching frequency, ramp slope compensation of $0.9V/T$ is utilized. This ramp compensation is summed to the current sense amplifier output and compared to the error amplifier output by the PWM comparator. When the sum of the current sense amplifier output and the slope compensation signal exceeds the EA output voltage, the RS Flip-Flop is reset and the HS MOSFET is turned off.

When the HS MOSFET turns off, the synchronous LS MOSFET turns on until the next clock cycle begins. There is a “dead time” between the HS turn-off and LS turn-on that prevents the switches from “shooting through” across the input supply to ground.

For one whole cycle, if the sum of the current sense amplifier output and the slope compensation signal does not exceed the EA output, then the falling edge of the oscillator clock will reset the Flip-Flop, forcing the MOSFET to turn off.

The voltage loop is compensated internally.

Enable

The enable (EN) input allows the user control for turning the regulator on or off. The AP65111 has an internal pull-down resistor on the EN pin, and when the EN is not actively pulled up the part will turn off.

Quiescent Current

Above the EN rising threshold, the internal regulator is turned on and the quiescent current can be measured when $V_{FB} > 0.8V$.

Automated No-Load and Light-Load Operation

The AP65111 operates in light-load high-efficiency mode during low-load current operation. The advantage of this light-load efficiency mode is that there are lower power losses in these conditions. The AP65111 automatically detects the inductor's valley current and enters the light-load high-efficiency mode when the value falls below zero amperes. Once the inductor's valley current exceeds zero amperes, the AP65111 will transition from light-load high-efficiency mode to continuous PWM mode.

Application Information (Continued)

Current Limit Protection

In order to reduce the total power dissipation and to protect the application, AP65111 has cycle-by-cycle current limiting implementation. The voltage drop across the internal high-side MOSFET is sensed and compared with the internally set current limit threshold. This voltage drop is sensed at about 30ns after the HS turns on. When the peak inductor current exceeds the set current limit threshold, current limit protection is activated. When the FB pin voltage drops below 0.4V, the device will enter Hiccup mode and periodically restart the part. This protection mode greatly reduces the power dissipated on-chip, and reduces the thermal stress to help protect the device. AP65111 will exit Hiccup mode when the overcurrent condition is resolved.

Undervoltage Lockout (UVLO)

Undervoltage Lockout is implemented to protect the IC from insufficient input voltages. The AP65111 has a UVLO comparator that monitors the input voltage and the internal bandgap reference. If the input voltage falls below 4.05V, the AP65111 will latch the undervoltage fault. In this event, the output will be pulled low and power has to be re-cycled to reset the UVLO fault.

Overvoltage Protection

When the AP65111 FB pin exceeds 115% of the 0.8V nominal regulation voltage, the overvoltage comparator is tripped and the internal regulator will stop switching. The V_{OUT} will stay at high-voltage at the tripped point, and be slowly discharged by the output capacitance.

Thermal Shutdown

The AP65111 has on-chip thermal protection that prevents damage to the IC when the die temperature exceeds safe margins. It implements thermal sensing to monitor the operating junction temperature of the IC. Once the die temperature rises to approximately +160°C, the thermal protection feature will be activated. The internal thermal sense circuitry turns off the IC, protecting the power switch from damage. A hysteresis in the thermal sense circuit allows the device to cool down to approximately +20°C before the IC is enabled again through soft-start. This thermal hysteresis feature prevents undesirable oscillations of the thermal protection circuit.

Setting the Output Voltage

The output voltage can be adjusted from 0.8V using an external resistor divider. Table 1 shows a list of resistor selection for common output voltages. A serial resistor, R_T, is also recommended for improving the system stability, especially for low V_{OUT} (<3.3V). An optional CFF of 10pF to 470pF could be used to boost the phase margin. Resistor R₁ is selected based on a design trade-off between efficiency and output voltage accuracy. For high values of R₁, there is less current consumption in the feedback network. R₁ can be determined by the following equation:

$$R_1 = R_2 \cdot \left(\frac{V_{OUT}}{0.8} - 1 \right)$$

Figure 2 Feedback Divider Network

V _{OUT} (V)	R ₁ (kΩ)	R ₂ (kΩ)	R _T (kΩ)	L ₁ (μH)
1.05	10	32.4	150	2.2
1.2	15	30.1	130	2.2
1.8	40.2	32.4	100	3.3
2.5	40.2	19.1	59	4.7
3.3	40.2	13	59	6.5
5	40.2	7.68	59	6.5

Table 1 Recommended Component Selection

Application Information (Cont.)

Inductor

Calculating the inductor value is a critical factor in designing a buck converter. For most designs, the following equation can be used to calculate the inductor value:

$$L = \frac{V_{OUT} \cdot (V_{IN} - V_{OUT})}{V_{IN} \cdot \Delta I_L \cdot f_{SW}}$$

Where ΔI_L represents the inductor ripple current and f_{SW} is the buck converter switching frequency.

The inductor ripple current should be 30% to 40% of the maximum load current. The maximum inductor peak current is calculated from:

$$I_{L(MAX)} = I_{LOAD} + \frac{\Delta I_L}{2}$$

Peak current determines the required saturation current rating, which influences the size of the inductor. Saturating the inductor decreases the converter efficiency, while increasing the temperatures of the inductor and the internal MOSFETs. Hence, choosing an inductor with appropriate saturation current rating is important.

A 1 μ H to 10 μ H inductor with a DC current rating of at least 25% higher than the maximum load current is recommended for most applications. To reach the highest efficiency, the inductor's DC resistance should be less than 20m Ω . Use a larger inductance to improve efficiency under light-load conditions.

Input Capacitor

The input capacitor reduces the surge current drawn from the input supply and the switching noise from the device. The input capacitor has to sustain the ripple current produced during the on-time of the upper MOSFET. It must have a low ESR to minimize losses.

The RMS current rating of the input capacitor is a critical parameter that must be higher than the RMS input current. As a rule of thumb, select an input capacitor that has an RMS rating greater than half of the maximum load current.

Due to large di/dt through the input capacitors, electrolytic or ceramics should be used. If a tantalum must be used, it must be surge-protected. Otherwise, capacitor failure could occur. For most applications, a 10/22 μ F ceramic capacitor is sufficient, and a 0.1 μ F serial capacitor is recommended for improving stability.

Output Capacitor

The output capacitor keeps the output voltage ripple minimal, ensures feedback loop stability and reduces the overshoot of the output voltage. The output capacitor is a basic component for the fast response of the power supply. In fact, during load transient, it supplies the current to the load for the first few microseconds. The converter recognizes the load transient and sets the duty cycle to maximum, but the current slope is limited by the inductor value.

ESR of the output capacitor dominates the output voltage ripple. The amount of ripple can be calculated from the equation below:

$$V_{out_capacitor} = \Delta I_{inductor} * ESR$$

An output capacitor with ample capacitance and low ESR is the best option. For most applications, a 22 μ F ceramic capacitor will be sufficient.

$$C_o = \frac{L(I_{out} + \frac{\Delta I_{inductor}}{2})^2}{(\Delta V + V_{out})^2 - V_{out}^2}$$

Where ΔV represents the maximum output voltage overshoot.

Application Information (Cont.)

PC Board Layout

This is a high switching frequency converter. Thus, attention must be paid to the switching current's interference in the layout. The switching current from one power device to another can generate voltage transients across the impedances of the interconnecting bond wires and circuit traces. These interconnecting impedances should be minimized by using wide, short-printed circuit traces.

Figure 3 PC Board Layout

External Bootstrap Diode

It is recommended that an external bootstrap diode be added when the input voltage is no greater than 5V or the 5V rail is available in the system. This helps to improve the efficiency of the regulator. This solution is also applicable for $D > 65\%$. The bootstrap diode can be a low-cost device such as BAT54 or a Schottky that has a low V_F . See below for Diodes Incorporated's recommended diodes.

LIFE SUPPORT

Diodes Incorporated products are specifically not authorized for use as critical components in life support devices or systems without the express written approval of the Chief Executive Officer of Diodes Incorporated. As used herein:

A. Life support devices or systems are devices or systems which:

1. are intended to implant into the body, or
2. support or sustain life and whose failure to perform when properly used in accordance with instructions for use provided in the labeling can be reasonably expected to result in significant injury to the user.

B. A critical component is any component in a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or to affect its safety or effectiveness.

Customers represent that they have all necessary expertise in the safety and regulatory ramifications of their life support devices or systems, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of Diodes Incorporated products in such safety-critical, life support devices or systems, notwithstanding any devices- or systems-related information or support that may be provided by Diodes Incorporated. Further, Customers must fully indemnify Diodes Incorporated and its representatives against any damages arising out of the use of Diodes Incorporated products in such safety-critical, life support devices or systems.
