What is short circuit protection latch type?

When the load current reaches a certain fixed value, the short circuit protection function activates to completely cut off the load current and keep the PhotoMOS turned off.

The short circuit protection inside the PhotoMOS instantaneously (Typ. 50 μ s) and completely cuts off the load current.

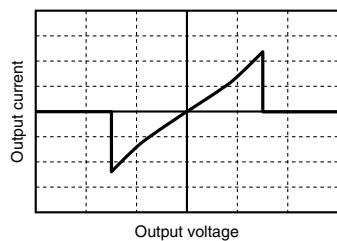

This protects any circuits that follow the PhotoMOS from excess current.

There is almost no heating of the PhotoMOS, which prevents it from becoming damaged. To restore the function of the PhotoMOS turn off the input current and then turn it back on.

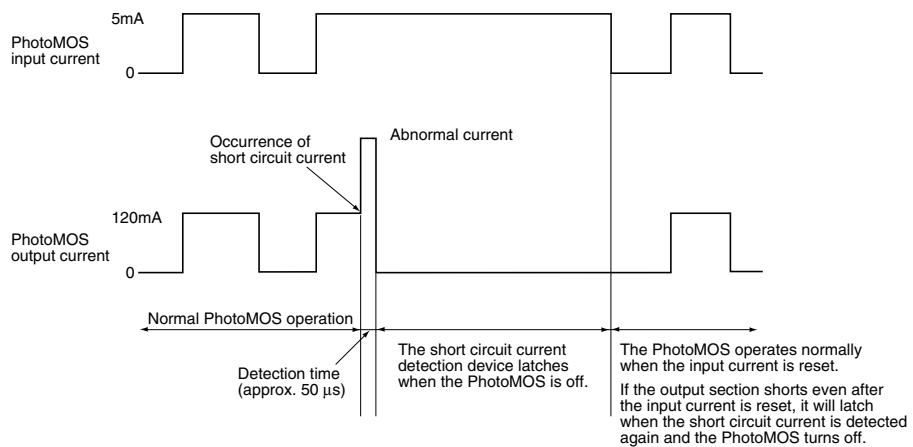

In order to operate the short circuit protection function, ensure that the input current is at least $I_F = 5$ mA.
