

UCC21750-Q1 适用于 SiC/IGBT 并具有主动保护、隔离式模拟感应和高 CMTI 的 10A 拉电流/灌电流增强型隔离式单通道栅极驱动器

1 特性

- 5.7kV_{RMS} 单通道隔离式栅极驱动器
- 符合面向汽车应用的 AEC-Q100 标准
 - 器件温度等级 1：-40°C 至 125°C 环境温度范围
 - 器件 HBM ESD 分类等级 3A
 - 器件 CDM ESD 分级等级 C3
- 高达 2121V_{pk} 的 SiC MOSFET 和 IGBT
- 33V 最大输出驱动电压 (VDD - VEE)
- ±10A 驱动强度和分离输出
- 150V/ns 最小 CMTI
- 具有 200ns 快速响应时间的 DESAT 保护
- 4A 内部有源米勒钳位
- 发生故障时的 400mA 软关断
- 具有 PWM 输出的隔离式模拟传感器
 - 采用 NTC、PTC 或热敏二极管的温度感应
 - 高电压直流链路或相电压
- 过流警报 $\overline{\text{FLT}}$ 和通过 $\overline{\text{RST/EN}}$ 重置
- 针对 $\overline{\text{RST/EN}}$ 的快速启用和禁用响应
- 抑制输入引脚上的 <40ns 噪声瞬态和脉冲
- RDY 上的 12V VDD UVLO (具有电源正常指示功能)
- 具有高达 5V 过冲/欠冲瞬态电压抗扰度的输入/输出
- 130 ns (最大) 传播延迟和 30 ns (最大) 脉冲/器件间偏移
- SOIC-16 DW 封装, 爬电距离和间隙 > 8mm
- 工作结温范围: -40°C 至 +150°C
- 安全相关认证:
 - 符合 DIN EN IEC 60747-17 (VDE 0884-17) 标准的增强型绝缘
 - UL 1577 组件认证计划

2 应用

- 适用于 EV 的牵引逆变器
- 车载充电器和充电桩
- 用于 HEV/EV 的直流/直流转换器

3 说明

UCC21750-Q1 是一款电隔离单通道栅极驱动器, 设计用于直流工作电压高达 2121V 的 SiC MOSFET 和 IGBT, 具有先进的保护功能、出色的动态性能和稳健性。UCC21750-Q1 具有高达 ±10A 的峰值拉电流和灌电流。

输入侧通过 SiO₂ 电容隔离技术与输出侧相隔离, 支持高达 1.5kV_{RMS} 的工作电压、12.8kV_{PK} 的浪涌抗扰度, 隔离层寿命超过 40 年, 并提供较低的器件间偏移, 共模噪声抗扰度 (CMTI) 大于 150V/ns。

UCC21750-Q1 包括先进的保护特性, 如快速过流和短路检测、分流电流检测支持、故障报告、有源米勒钳位、输入和输出侧电源 UVLO (用于优化 SiC 和 IGBT 开关行为和稳健性)。可以利用隔离式模拟至 PWM 传感器更轻松感测温度或电压, 从而进一步提高驱动器的多功能性并简化系统设计工作量、尺寸和成本。

器件信息

| 器件型号 | 封装 ⁽¹⁾ | 封装尺寸 (标称值) |
|-------------|-------------------|----------------|
| UCC21750-Q1 | DW SOIC-16 | 10.3mm × 7.5mm |

(1) 如需了解所有可用封装, 请参阅数据表末尾的可订购产品附录。

5 Pin Configuration and Functions

图 5-1. UCC21750-Q1 DW SOIC (16) Top View

表 5-1. Pin Functions

| PIN | | I/O ⁽¹⁾ | DESCRIPTION |
|--------|-----|--------------------|---|
| NAME | NO. | | |
| AIN | 1 | I | Isolated analog sensing input, parallel a small capacitor to COM for better noise immunity. Tie to COM if unused. |
| DESAT | 2 | I | Desaturation current protection input. Tie to COM if unused. |
| COM | 3 | P | Common ground reference, connecting to emitter pin for IGBT and source pin for SiC-MOSFET. |
| OUTH | 4 | O | Gate driver output pull up. |
| VDD | 5 | P | Positive supply rail for gate drive voltage. Bypass with a >10- μ F capacitor to COM to support specified gate driver source peak current capability. Place decoupling capacitor close to the pin. |
| OUTL | 6 | O | Gate driver output pull down. |
| CLMPI | 7 | I | Internal Active miller clamp, connecting this pin directly to the gate of the power transistor. Leave floating or tie to VEE if unused. |
| VEE | 8 | P | Negative supply rail for gate drive voltage. Bypass with a >10- μ F capacitor to COM to support specified gate driver sink peak current capability. Place decoupling capacitor close to the pin. |
| GND | 9 | P | Input power supply and logic ground reference. |
| IN+ | 10 | I | Non-inverting gate driver control input. Tie to VCC if unused. |
| IN- | 11 | I | Inverting gate driver control input. Tie to GND if unused. |
| RDY | 12 | O | Power good for VCC-GND and VDD-COM. RDY is open drain configuration and can be paralleled with other RDY signals. |
| FLT | 13 | O | Active low fault alarm output upon over current or short circuit. FLT is in open drain configuration and can be paralleled with other faults. |
| RST/EN | 14 | I | The RST/EN serves two purposes: 1) Enable / shutdown of the output side. The FET is turned off by a regular turn-off, if terminal EN is set to low; 2) Resets the DESAT condition signaled on FLT pin if terminal RST/EN is set to low for more than 1000 ns. A reset of signal FLT is asserted at the rising edge of terminal RST/EN. For automatic RESET function, this pin only serves as an EN pin. Enable / shutdown of the output side. The FET is turned off by a regular turn-off, if terminal EN is set to low. |
| VCC | 15 | P | Input power supply from 3 V to 5.5 V. Bypass with a >1- μ F capacitor to GND. Place decoupling capacitor close to the pin. |
| APWM | 16 | O | Isolated Analog Sensing PWM output. Leave floating if unused. |

(1) P = Power, G = Ground, I = Input, O = Output

6 Specifications

6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

| PARAMETER | | MIN | MAX | UNIT | |
|--|--------------------------------|--|-----------|---------|---|
| VCC | VCC – GND | - 0.3 | 6 | V | |
| VDD | VDD – COM | - 0.3 | 36 | V | |
| VEE | VEE – COM | - 17.5 | 0.3 | V | |
| V _{MAX} | VDD – VEE | - 0.3 | 36 | V | |
| IN+, IN -, $\overline{\text{RST}}/\text{EN}$ | | DC | GND – 0.3 | VCC | V |
| | | Transient, less than 100 ns ⁽²⁾ | GND – 5.0 | VCC+5.0 | V |
| DESAT | Reference to COM | COM – 0.3 | VDD+0.3 | V | |
| AIN | Reference to COM | - 0.3 | 5 | V | |
| OUTH, OUTL, CLMPI | | DC | VEE – 0.3 | VDD | V |
| | | Transient, less than 100 ns ⁽²⁾ | VEE – 5.0 | VDD+5.0 | V |
| RDY, FLT, APWM | | GND – 0.3 | VCC | V | |
| I _{FLT} , I _{RDY} | FLT, and RDY pin input current | | 20 | mA | |
| I _{APWM} | APWM pin output current | | 20 | mA | |
| T _J | Junction temperature range | - 40 | 150 | °C | |
| T _{stg} | Storage temperature range | - 65 | 150 | °C | |

- (1) Operation outside the *Absolute Maximum Ratings* may cause permanent device damage. *Absolute Maximum Ratings* do not imply functional operation of the device at these or any other conditions beyond those listed under *Recommended Operating Conditions*. If outside the *Recommended Operating Conditions* but within the *Absolute Maximum Ratings*, the device may not be fully functional, and this may affect device reliability, functionality, performance, and shorten the device lifetime.
- (2) Values are verified by characterization on bench.

6.2 ESD Ratings

| | | VALUE | UNIT |
|--------------------|-------------------------|---|-------|
| V _(ESD) | Electrostatic discharge | Human-body model (HBM), per AEC Q100-002 ⁽¹⁾ | ±4000 |
| | | Charged-device model (CDM), per AEC Q100-011 | ±1500 |

- (1) AEC Q100-002 indicates that HBM stressing shall be in accordance with the ANSI/ESDA/JEDEC JS-001 specification.

6.3 Recommended Operating Conditions

| PARAMETER | | MIN | MAX | UNIT | |
|--|--|--------------------------|---------|---------|---|
| VCC | VCC – GND | 3.0 | 5.5 | V | |
| VDD | VDD – COM | 13 | 33 | V | |
| V _{MAX} | VDD – VEE | - | 33 | V | |
| IN+, IN -, $\overline{\text{RST}}/\text{EN}$ | Reference to GND | High level input voltage | 0.7×VCC | VCC | V |
| | | Low level input voltage | 0 | 0.3×VCC | |
| AIN | Reference to COM | 0.6 | 4.5 | V | |
| t _{RST/EN} | Minimum pulse width that reset the fault | 800 | | ns | |
| T _A | Ambient temperature | - 40 | 125 | °C | |
| T _J | Junction temperature | - 40 | 150 | °C | |

6.4 Thermal Information

| THERMAL METRIC ⁽¹⁾ | | UCC21750-Q1 | UNIT |
|-------------------------------|--|-------------|------|
| | | DW (SOIC) | |
| | | 16 PINS | |
| $R_{\theta JA}$ | Junction-to-ambient thermal resistance | 68.3 | °C/W |
| $R_{\theta JC(top)}$ | Junction-to-case (top) thermal resistance | 27.5 | °C/W |
| $R_{\theta JB}$ | Junction-to-board thermal resistance | 32.9 | °C/W |
| ψ_{JT} | Junction-to-top characterization parameter | 14.1 | °C/W |
| ψ_{JB} | Junction-to-board characterization parameter | 32.3 | °C/W |

(1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics](#) application report.

6.5 Power Ratings

| PARAMETER | TEST CONDITIONS | Value | UNIT |
|-----------|---|--|------|
| P_D | Maximum power dissipation (both sides) | 985 | mW |
| P_{D1} | Maximum power dissipation by transmitter side | VCC = 5 V, VDD - COM = 20 V, COM - VEE = 5 V, IN+/- = 5 V, 150 kHz, 50% Duty Cycle for a 10-nF load, T _a = 25°C | 20 |
| P_{D2} | Maximum power dissipation by receiver side | | 965 |

6.6 Insulation Specifications

| PARAMETER | TEST CONDITIONS | VALUE | UNIT |
|--|--|--|-----------------------|
| GENERAL | | | |
| CLR | External clearance ⁽¹⁾ | Shortest terminal-to-terminal distance through air | > 8 mm |
| CPG | External creepage ⁽¹⁾ | Shortest terminal-to-terminal distance across the package surface | > 8 mm |
| DTI | Distance through the insulation | Minimum internal gap (Internal clearance) of the double insulation (2 × 0.0085 mm) | > 17 μm |
| CTI | Comparative tracking index | DIN EN 60112 (VDE 0303-11); IEC 60112 | > 600 V |
| | Material group | According to IEC 60664 - 1 | I |
| | Overvoltage Category per IEC 60664 - 1 | Rated mains voltage ≤ 300 V _{RMS} | I-IV |
| | | Rated mains voltage ≤ 600 V _{RMS} | I-IV |
| | | Rated mains voltage ≤ 1000 V _{RMS} | I-III |
| DIN EN IEC 60747-17 (VDE 0884-17)⁽²⁾ | | | |
| V_{IORM} | Maximum repetitive peak isolation voltage | AC voltage (bipolar) | 2121 V _{PK} |
| V_{IOWM} | Maximum isolation working voltage | AC voltage (sine wave) Time dependent dielectric breakdown (TDDB) test | 1500 V _{RMS} |
| | | DC voltage | 2121 V _{DC} |
| V_{IMP} | Maximum impulse voltage | Tested in air, 1.2/50- μ s waveform per IEC 62368-1 | 8000 V _{PK} |
| V_{IOTM} | Maximum transient isolation voltage | $V_{TEST}=V_{IOTM}$, t = 60 s (qualification test) | 8000 V _{PK} |
| | | $V_{TEST}=1.2 \times V_{IOTM}$, t = 1 s (100% production test) | |
| V_{IOSM} | Maximum surge isolation voltage ⁽³⁾ | Test method per IEC 62368-1, 1.2/50 μ s waveform | 12800 V _{PK} |

6.6 Insulation Specifications (续)

| PARAMETER | | TEST CONDITIONS | VALUE | UNIT |
|------------------|---|--|--------------------|------------------|
| Q _{pd} | Apparent charge ⁽⁴⁾ | Method a: After I/O safety test subgroup 2/3, V _{ini} = V _{IOTM} , t _{ini} = 60 s; V _{pd(m)} = 1.2 × V _{IORM} = 2545 V _{PK} , t _m = 10 s | ≤ 5 | pC |
| | | Method a: After environmental tests subgroup 1, V _{ini} = V _{IOTM} , t _{ini} = 60 s; V _{pd(m)} = 1.6 × V _{IORM} = 3394 V _{PK} , t _m = 10 s | ≤ 5 | |
| | | Method b1: At routine test (100% production) and preconditioning (type test) V _{ini} = V _{IOTM} , t _{ini} = 1 s; V _{pd(m)} = 1.875 × V _{IORM} = 3977 V _{PK} , t _m = 1 s | ≤ 5 | |
| C _{IO} | Barrier capacitance, input to output ⁽⁵⁾ | V _{IO} = 0.5 sin (2 π ft), f = 1 MHz | ~ 1 | pF |
| R _{IO} | Insulation resistance, input to output ⁽⁵⁾ | V _{IO} = 500 V, T _A = 25°C | ≥ 10 ¹² | Ω |
| | | V _{IO} = 500 V, 100°C ≤ T _A ≤ 125°C | ≥ 10 ¹¹ | |
| | | V _{IO} = 500 V at T _S = 150°C | ≥ 10 ⁹ | |
| | Pollution degree | | 2 | |
| | Climatic category | | 40/125/21 | |
| UL 1577 | | | | |
| V _{ISO} | Withstand isolation voltage | V _{TEST} = V _{ISO} = 5700 V _{RMS} , t = 60 s (qualification); V _{TEST} = 1.2 × V _{ISO} = 6840 V _{RMS} , t = 1 s (100% production) | 5700 | V _{RMS} |

- Apply creepage and clearance requirements according to the specific equipment isolation standards of an application. Care must be taken to maintain the creepage and clearance distance of a board design to ensure that the mounting pads of the isolator on the printed circuit board (PCB) do not reduce this distance. Creepage and clearance on a PCB become equal in certain cases. Techniques such as inserting grooves and ribs on the PCB are used to help increase these specifications.
- This coupler is suitable for safe electrical insulation only within the safety ratings. Compliance with the safety ratings shall be ensured by means of suitable protective circuits.
- Testing is carried out in air or oil to determine the intrinsic surge immunity of the isolation barrier.
- Apparent charge is electrical discharge caused by a partial discharge (pd).
- All pins on each side of the barrier tied together creating a two-terminal device.

6.7 Safety Limiting Values

Safety limiting⁽¹⁾ intends to minimize potential damage to the isolation barrier upon failure of input or output circuitry. A failure of the I/O can allow low resistance to ground or the supply and, without current limiting, dissipate sufficient power to overheat the die and damage the isolation barrier, potentially leading to secondary system failures.

| PARAMETER | | TEST CONDITIONS | MIN | TYP | MAX | UNIT |
|----------------|---|--|-----|-----|------|------|
| I _S | Safety input, output, or supply current | R _{θJA} = 68.3°C/W, V _{DD} = 15 V, V _{EE} = -5 V, T _J = 150°C, T _A = 25°C | | | 61 | mA |
| | | R _{θJA} = 68.3°C/W, V _{DD} = 20 V, V _{EE} = -5 V, T _J = 150°C, T _A = 25°C | | | 49 | |
| P _S | Safety input, output, or total power | R _{θJA} = 68.3°C/W, V _{DD} = 20 V, V _{EE} = -5 V, T _J = 150°C, T _A = 25°C | | | 1220 | mW |
| T _S | Safety temperature | | | | 150 | °C |

- The safety-limiting constraint is the maximum junction temperature specified in the data sheet. The power dissipation and junction-to-air thermal impedance of the device installed in the application hardware determines the junction temperature. The assumed junction-to-air thermal resistance in the [Thermal Information](#) table is that of a device installed on a high-K test board for leaded surface-mount packages. The power is the recommended maximum input voltage times the current. The junction temperature is then the ambient temperature plus the power times the junction-to-air thermal resistance.

6.8 Electrical Characteristics

VCC = 3.3 V or 5.0 V, 1-μF capacitor from VCC to GND, VDD - COM = 20 V, 18 V or 15 V, COM - VEE = 0 V, 5 V, 8 V or 15 V, C_L = 100 pF, -40°C < T_J < 150°C (unless otherwise noted)^{(1) (2)}.

| PARAMETER | TEST CONDITIONS | MIN | TYP | MAX | UNIT |
|-------------------------------------|-----------------|-----|-----|-----|------|
| VCC UVLO THRESHOLD AND DELAY | | | | | |

6.8 Electrical Characteristics (续)

VCC = 3.3 V or 5.0 V, 1- μ F capacitor from VCC to GND, VDD - COM = 20 V, 18 V or 15 V, COM - VEE = 0 V, 5 V, 8 V or 15 V, C_L = 100 pF, - 40°C < T_J < 150°C (unless otherwise noted)^{(1) (2)}.

7.2 Input Deglitch Filter

In order to increase the robustness of gate driver over noise transient and accidental small pulses on the input pins, that is, IN+, IN-, $\overline{\text{RST/EN}}$, a 40-ns deglitch filter is designed to filter out the transients and make sure there is no faulty output responses or accidental driver malfunctions. When the IN+ or IN- PWM pulse is smaller than the input deglitch filter width, T_{INFIL} , there is no responses on OUT drive signal. 图 7-3 and 图 7-4 show the IN+ pin ON and OFF pulse deglitch filter effect. 图 7-5 and 图 7-6 show the IN- pin ON and OFF pulse deglitch filter effect.

8 Detailed Description

8.1 Overview

The UCC21750-Q1 device is an advanced isolated gate driver with state-of-art protection and sensing features for SiC MOSFETs and IGBTs. The device can support up to 2121-V DC operating voltage based on SiC MOSFETs and IGBTs, and can be used to above 10-kW applications, such as HEV/EV traction inverter, motor drive, on-board and off-board battery charger, solar inverter, and so forth. The galvanic isolation is implemented by the capacitive isolation technology, which can realize a reliable reinforced isolation between the low voltage DSP/MCU and high voltage side.

The ± 10 -A peak sink and source current of the UCC21750-Q1 can drive the SiC MOSFET modules and IGBT modules directly without an extra buffer. The driver can also be used to drive higher power modules or parallel modules with external buffer stage. The input side is isolated with the output side with a reinforced isolation barrier based on capacitive isolation technology. The device can support up to 1.5-kV_{RMS} working voltage, 12.8-kV_{PK} surge immunity with longer than 40 years isolation barrier life. The strong drive strength helps to switch the device fast and reduce the switching loss, while the 150-V/ns minimum CMTI assures the reliability of the system with fast switching speed. The small propagation delay and part-to-part skew can minimize the deadtime setting, so the conduction loss can be reduced.

The device includes extensive protection and monitor features to increase the reliability and robustness of the SiC MOSFET and IGBT based systems. The 12-V output side power supply UVLO is suitable for switches with gate voltage ≥ 15 V. The active miller clamp feature prevents the false turn on causing by miller capacitance during fast switching. The device has the state-of-art DESAT detection time and fault reporting function to the low voltage side DSP/MCU. The soft turn-off is triggered when the DESAT fault is detected, minimizing the short circuit energy while reducing the overshoot voltage on the switches.

The isolated analog to PWM sensor can be used as switch temperature sensing, DC bus voltage sensing, auxiliary power supply sensing, and so forth. The PWM signal can be fed directly to DSP/MCU or through a low-pass-filter as an analog signal.

held in LOW state. The split output of the driver stage is depicted in 图 8-1. The driver has rail-to-rail output by implementing a hybrid pull-up structure with a P-Channel MOSFET in parallel with an N-Channel MOSFET, and an N-Channel MOSFET to pulldown. The pull-up NMOS is the same as the pull down NMOS, so the on resistance R_{NMOS} is the same as R_{OL} . The hybrid pull-up structure delivers the highest peak-source current when it is most needed, during the miller plateau region of the power semiconductor turn-on transient. The R_{OH} in 图 8-1 represents the on-resistance of the pull-up P-Channel MOSFET. However, the effective pull-up resistance is much smaller than R_{OH} . Because the pull-up N-Channel MOSFET has much smaller on-resistance than the P-Channel MOSFET, the pull-up N-Channel MOSFET dominates most of the turn-on transient, until the voltage on OUTH pin is about 3 V below VDD voltage. The effective resistance of the hybrid pull-up structure during this period is about $2 \times R_{OL}$. Then the P-Channel MOSFET pulls up the OUTH voltage to VDD rail. The low pull-up impedance results in strong drive strength during the turn-on transient, which shortens the charging time of the input capacitance of the power semiconductor and reduces the turn on switching loss.

The pull-down structure of the driver stage is implemented solely by a pull-down N-Channel MOSFET. This MOSFET can ensure the OUTL voltage be pulled down to VEE rail. The low pull-down impedance not only results in high sink current to reduce the turn-off time, but also helps to increase the noise immunity considering the miller effect.

图 8-1. Gate Driver Output Stage

8.3.3 VCC and VDD Undervoltage Lockout (UVLO)

The UCC21750-Q1 implements the internal UVLO protection feature for both input and output power supplies VCC and VDD. When the supply voltage is lower than the threshold voltage, the driver output is held as LOW. The output only goes HIGH when both VCC and VDD are out of the UVLO status. The UVLO protection feature not only reduces the power consumption of the driver itself during low power supply voltage condition, but also increases the efficiency of the power stage. For SiC MOSFET and IGBT, the on-resistance reduces while the gate-source voltage or gate-emitter voltage increases. If the power semiconductor is turned on with a low VDD value, the conduction loss increases significantly and can lead to a thermal issue and efficiency reduction of the power stage. The UCC21750-Q1 implements a 12-V threshold voltage of VDD UVLO, with 800-mV hysteresis. This threshold voltage is suitable for both SiC MOSFET and IGBT.

The UVLO protection block features with hysteresis and deglitch filter, which help to improve the noise immunity of the power supply. During the turn-on and turn-off switching transient, the driver sources and sinks a peak transient current from the power supply, which can result in sudden voltage drop of the power supply. With hysteresis and UVLO deglitch filter, the internal UVLO protection block ignores small noises during the normal switching transients.

The timing diagrams of the UVLO feature of VCC and VDD are shown in 图 7-8, and 图 7-9. The RDY pin on the input side is used to indicate the power good condition. The RDY pin is open drain. During UVLO condition, the RDY pin is held in low status and connected to GND. Normally the pin is pulled up externally to VCC to indicate the power good. The AIN-APWM function stops working during the UVLO status. The APWM pin on the input side is held LOW.

8.3.4 Active Pulldown

The UCC21750-Q1 implements an active pulldown feature to ensure the OUTH/OUTL pin clamping to VEE when the VDD is open. The OUTH/OUTL pin is in high-impedance status when VDD is open, the active pulldown feature can prevent the output be false turned on before the device is back to control.

图 8-2. Active Pulldown

8.3.5 Short Circuit Clamping

During short circuit condition, the miller capacitance can cause a current sinking to the OUTH/OUTL/CLMPI pin due to the high dV/dt and boost the OUTH/OUTL/CLMPI voltage. The short circuit clamping feature of the UCC21750-Q1 can clamp the OUTH/OUTL/CLMPI pin voltage to be slightly higher than VDD, which can protect the power semiconductors from a gate-source and gate-emitter overvoltage breakdown. This feature is realized by an internal diode from the OUTH/OUTL/CLMPI to VDD.

8.3.7 Desaturation (DESAT) Protection

The UCC21750-Q1 implements a fast overcurrent and short circuit protection feature to protect the IGBT module from catastrophic breakdown during fault. The DESAT pin of the device has a typical 9-V threshold with respect to COM, source or emitter of the power semiconductor. When the input is in floating condition, or the output is held in low state, the DESAT pin is pulled down by an internal MOSFET and held in LOW state, which prevents the overcurrent and short circuit fault from false triggering. The internal current source of the DESAT pin is activated only during the driver ON state, which means the overcurrent and short circuit protection feature only works when the power semiconductor is in on state. The internal pulldown MOSFET helps to discharge the voltage of DESAT pin when the power semiconductor is turned off. The UCC21750-Q1 features a 200-ns internal leading edge blanking time after the OUTH switches to high state. The internal current source is activated to charge the external blanking capacitor after the internal leading edge blanking time. The typical value of the internal current source is 500 μ A.

图 8-5. DESAT Protection

8.3.8 Soft Turn-Off

The UCC21750-Q1 initiates a soft turn-off when the overcurrent and short circuit protection is triggered. When the overcurrent and short circuit fault happens, the IGBT transits from the active region to the desaturation region very fast. The channel current is controlled by the gate voltage and decreasing in a soft manner, thus the overshoot of the IGBT is limited and prevents the overvoltage breakdown. There is a tradeoff between the overshoot voltage and short circuit energy. The turn off speed must be slow to limit the overshoot voltage, but the shutdown time must not be too long that the large energy dissipation can breakdown the device. The 400-mA soft turn-off current of the UCC21750-Q1 makes sure the power switches is safely turned off during short circuit events. The timing diagram of soft turn-off shows in 图 7-10.

DSP/MCU to calculate the duty cycle, or filtered by a simple RC filter as an analog signal. The AIN voltage input range is from 0.6 V to 4.5 V, and the corresponding duty cycle of the APWM output ranges from 88% to 10%. The duty cycle increases linearly from 10% to 88% while the AIN voltage decreases from 4.5 V to 0.6 V. This action corresponds to the temperature coefficient of the negative temperature coefficient (NTC) resistor and thermal diode. When AIN is floating, the AIN voltage is 5 V and the APWM operates at 400 kHz with approximately 10% duty cycle. The accuracy of the duty cycle is $\pm 3\%$ across temperature without one time calibration. The accuracy can be improved using calibration. The accuracy of the internal current source I_{AIN} is $\pm 3\%$ across temperature.

The isolated analog to PWM signal feature can also support other analog signal sensing, such as the high voltage dc bus voltage, and so forth. The internal current source I_{AIN} must be taken into account when designing the potential divider if sensing a high voltage.

图 8-7. Isolated Analog to PWM Signal

8.4 Device Functional Modes

The 表 8-1 lists the device function.

表 8-1. Function Table

| INPUT | | | | | | | OUTPUT | | | | |
|-------|------|------|------|------|--------|-----|--------|-----|---------------|-------|------|

PU: Power Up ($V_{CC} \geq 2.85\text{ V}$, $V_{DD} \geq 13.1\text{ V}$, $V_{EE} \leq 0\text{ V}$); PD: Power Down ($V_{CC} \leq 2.35\text{ V}$, $V_{DD} \leq 9.9\text{ V}$); X: Irrelevant; P*: PWM Pulse; HiZ: High Impedance

9 Applications and Implementation

备注

以下应用部分中的信息不属于 TI 器件规格的范围，TI 不担保其准确性和完整性。TI 的客户应负责确定器件是否适用于其应用。客户应验证并测试其设计，以确保系统功能。

9.1 Application Information

The UCC21750-Q1 device is very versatile because of the strong drive strength, wide range of output power supply, high isolation ratings, high CMTI and superior protection and sensing features. The 1.5-kVRMS working voltage and 12.8-kVpk surge immunity can support up both SiC MOSFET and IGBT modules with DC bus voltage up to 2121 V. The device can be used in both low power and high power applications such as the traction inverter in HEV/EV, on-board charger and charging pile, motor driver, solar inverter, industrial power supplies and so forth. The device can drive the high power SiC MOSFET module, IGBT module or paralleled discrete device directly without external buffer drive circuit based on NPN/PNP bipolar transistor in totem-pole structure, which allows the driver to have more control to the power semiconductor and saves the cost and space of the board design. The UCC21750-Q1 can also be used to drive very high power modules or paralleled modules with external buffer stage. The input side can support power supply and microcontroller signal from 3.3 V to 5 V, and the device level shifts the signal to output side through reinforced isolation barrier. The device has wide output power supply range from 13 V to 33 V and support wide range of negative power supply. This feature allows the driver to be used in SiC MOSFET applications, IGBT application and many others. The 12-V UVLO benefits the power semiconductor with lower conduction loss and improves the system efficiency. As a reinforced isolated single channel driver, the device can be used to drive either a low-side or high-side driver.

The UCC21750-Q1 device features extensive protection and monitoring features, which can monitor, report and protect the system from various fault conditions.

- Fast detection and protection for the overcurrent and short circuit fault. The semiconductor is shutdown when the fault is detected and FLT pin is pulled down to indicate the fault detection. The device is latched unless reset signal is received from the RST/EN pin.
- Soft turn-off feature to protect the power semiconductor from catastrophic breakdown during overcurrent and short circuit fault. The shutdown energy can be controlled while the overshoot of the power semiconductor is limited.
- UVLO detection to protect the semiconductor from excessive conduction loss. After the device is detected to be in UVLO mode, the output is pulled down and RDY pin indicates the power supply is lost. The device is back to normal operation mode after the power supply is out of the UVLO status. The power good status can be monitored from the RDY pin.
- Analog signal sensing with isolated analog to PWM signal feature. This feature allows the device to sense the temperature of the semiconductor from the thermal diode or temperature sensing resistor, or dc bus voltage with resistor divider. A PWM signal is generated on the low voltage side with reinforced isolated from the high voltage side. The signal can be fed back to the microcontroller for the temperature monitoring, voltage monitoring and so forth.
- The active miller clamp feature protects the power semiconductor from false turn on.
- Enable and disable function through the RST/EN pin.
- Short circuit clamping.
- Active pulldown.

9.2 Typical Application

图 9-1 shows the typical application of a half bridge using two UCC21750-Q1 isolated gate drivers. The half bridge is a basic element in various power electronics applications such as traction inverter in HEV/EV to convert the DC current of the electric vehicle's battery to the AC current to drive the electric motor in the propulsion system. The topology can also be used in motor drive applications to control the operating speed and torque of the AC motors.

图 9-1. Typical Application Schematic

9.2.1 Design Requirements

The design of the power system for end equipment must consider some design requirements to ensure the reliable operation of the UCC21750-Q1 through the load range. The design considerations include the peak source and sink current, power dissipation, overcurrent and short circuit protection, AIN-APWM function for analog signal sensing and so forth.

A design example for a half bridge based on IGBT is given in this subsection. 表 9-1 shows the design parameters.

表 9-1. Design Parameters

| PARAMETER | VALUE |
|-----------------------------|---------------|
| Input supply voltage | 5 V |
| IN-OUT configuration | Non-inverting |
| Positive output voltage VDD | 15 V |
| Negative output voltage VEE | - 5 V |
| DC bus voltage | 800 V |
| Peak drain current | 300 A |
| Switching frequency | 50 kHz |
| Switch type | IGBT module |

9.2.2 Detailed Design Procedure

9.2.2.1 Input Filters for IN+, IN -, and RST/EN

In the applications of traction inverter or motor drive, the power semiconductors are in hard switching mode. With the strong drive strength of the UCC21750-Q1, the dV/dt can be high, especially for SiC MOSFET. Noise cannot

only be coupled to the gate voltage due to the parasitic inductance, but also to the input side as the non-ideal PCB layout and coupled capacitance.

The UCC21750-Q1 features a 40-ns internal deglitch filter to IN+, IN- and $\overline{RST/EN}$ pin. Any signal less than 40 ns can be filtered out from the input pins. For noisy systems, external low-pass filter can be added externally to the input pins. Adding low-pass filters to IN+, IN- and $\overline{RST/EN}$ pins can effectively increase the noise immunity and increase the signal integrity. When not in use, the IN+, IN- and $\overline{RST/EN}$ pins must not be floating. IN- must be tied to GND if only IN+ is used for non-inverting input to output configuration. The purpose of the low-pass filter is to filter out the high frequency noise generated by the layout parasitics. While choosing the low-pass filter resistors and capacitors, both the noise immunity effect and delay time must be considered according to the system requirements.

9.2.2.2 PWM Interlock of IN+ and IN-

The UCC21750-Q1 features the PWM interlock for IN+ and IN- pins, which can be used to prevent the phase leg shoot through issue. As shown in 表 8-1, the output is logic low while both IN+ and IN- are logic high. When only IN+ is used, IN- can be tied to GND. To use the PWM interlock function, the PWM signal of the other switch in the phase leg can be sent to the IN- pin. As shown in 图 9-2, the PWM_T is the PWM signal to top side switch, the PWM_B is the PWM signal to bottom side switch. For the top side gate driver, the PWM_T signal is given to the IN+ pin, while the PWM_B signal is given to the IN- pin; for the bottom side gate driver, the PWM_B signal is given to the IN+ pin, while PWM_T signal is given to the IN- pin. When both PWM_T and PWM_B signals are high, the outputs of both gate drivers are logic low to prevent the shoot through condition.

图 9-2. PWM Interlock for a Half Bridge

9.2.2.3 \overline{FLT} , RDY, and $\overline{RST/EN}$ Pin Circuitry

Both \overline{FLT} and RDY pin are open-drain output. The $\overline{RST/EN}$ pin has a 50-k Ω internal pulldown resistor, so the driver is in OFF status if the $\overline{RST/EN}$ pin is not pulled up externally. A 5 k Ω resistor can be used as pullup resistor for the \overline{FLT} , RDY and $\overline{RST/EN}$ pins.

To improve the noise immunity due to the parasitic coupling and common mode noise, low pass filters can be added between the \overline{FLT} , RDY and $\overline{RST/EN}$ pins and the microcontroller. A filter capacitor between 100 pF to 300 pF can be added.

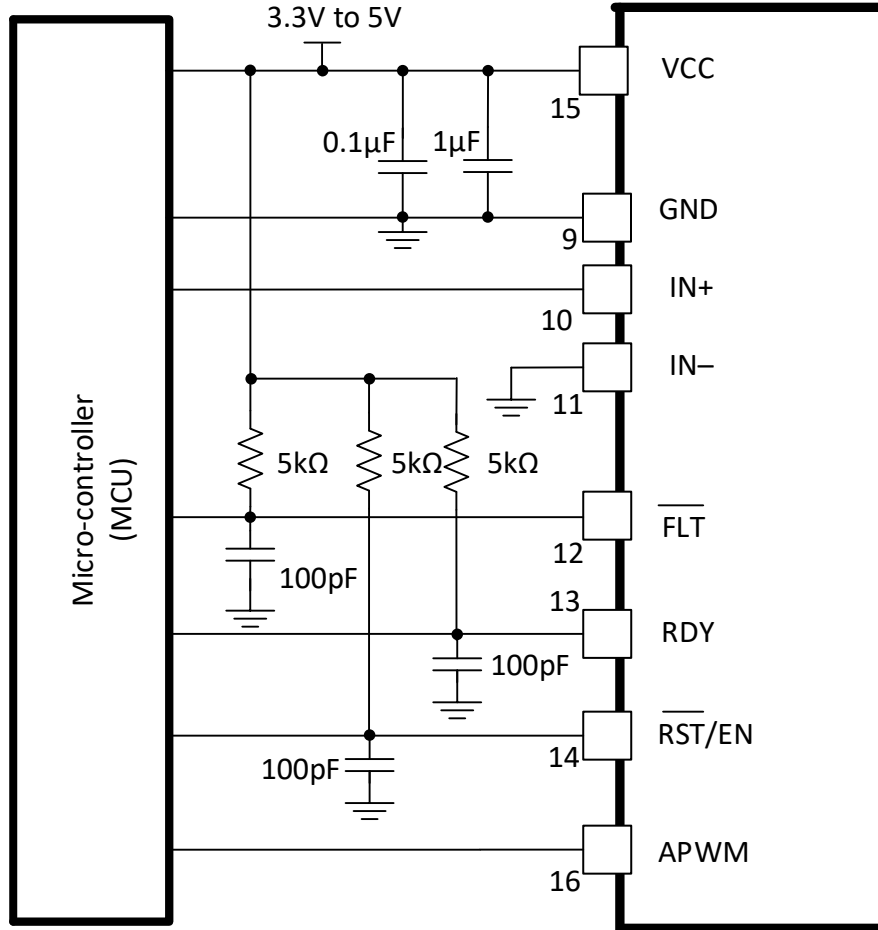

图 9-3. $\overline{\text{FLT}}$, RDY , and $\overline{\text{RST/EN}}$ Pins Circuitry

9.2.2.4 $\overline{\text{RST/EN}}$ Pin Control

The $\overline{\text{RST/EN}}$ pin has two functions. The pin is used to enable or shutdown the outputs of the driver and to reset the fault signaled on the $\overline{\text{FLT}}$ pin after DESAT is detected. $\overline{\text{RST/EN}}$ pin must to be pulled up to enable the device; when the pin is pulled down, the device is in disabled status. By default the driver is disabled with the internal $50\text{k}\Omega$ pulldown resistor at this pin.

When the driver is latched after DESAT is detected, the $\overline{\text{FLT}}$ pin and output are latched low and must be reset by the $\overline{\text{RST/EN}}$ pin. The microcontroller must send a signal to $\overline{\text{RST/EN}}$ pin after the fault to reset the driver. The driver does not respond until after the mute time t_{FLTMUTE} . The reset signal must be held low for at least t_{RSTFIL} after the mute time.

This pin can also be used to automatically reset the driver. The continuous input signal IN+ or IN- can be applied to $\overline{\text{RST/EN}}$ pin. There is no separate reset signal from the microcontroller when configuring the driver this way. If the PWM is applied to the non-inverting input IN+ , then IN+ can also be tied to $\overline{\text{RST/EN}}$ pin. If the PWM is applied to the inverting input IN- , then a NOT logic is needed between the PWM signal from the microcontroller and the $\overline{\text{RST/EN}}$ pin. Using either configuration results in the driver being reset in every switching cycle without an extra control signal from microcontroller tied to $\overline{\text{RST/EN}}$ pin. One must ensure the PWM off-time is greater than t_{RSTFIL} in order to reset the driver in cause of a DESAT fault.

图 9-4. Automatic Reset Control

9.2.2.5 Turn-On and Turn-Off Gate Resistors

The UCC21750-Q1 features split outputs OUTH and OUTL, which enables the independent control of the turn on and turn off switching speed. The turn on and turn off resistance determine the peak source and sink current, which controls the switching speed in turn. Meanwhile, the power dissipation in the gate driver must be considered to ensure the device is in the thermal limit. At first, the peak source and sink current are calculated as:

$$I_{\text{source_pk}} = \min\left(10\text{A}, \frac{V_{\text{DD}} - V_{\text{EE}}}{R_{\text{OH_EFF}} + R_{\text{ON}} + R_{\text{G_Int}}}\right)$$

$$I_{\text{sink_pk}} = \min\left(10\text{A}, \frac{V_{\text{DD}} - V_{\text{EE}}}{R_{\text{OL}} + R_{\text{OFF}} + R_{\text{G_Int}}}\right) \quad (1)$$

Where

- $R_{\text{OH_EFF}}$ is the effective internal pull up resistance of the hybrid pull-up structure, shown in 图 8-1, which is approximately $2 \times R_{\text{OL}}$, about 0.7Ω . This is the dominant resistance during the switching transient of the pull up structure.
- R_{OL} is the internal pulldown resistance, about 0.3Ω .
- R_{ON} is the external turn on gate resistance.
- R_{OFF} is the external turn off gate resistance.
- $R_{\text{G_Int}}$ is the internal resistance of the SiC MOSFET or IGBT module.

图 9-5. Output Model for Calculating Peak Gate Current

For example, for an IGBT module based system with the following parameters:

- $Q_g = 3300 \text{ nC}$
- $R_{G_Int} = 1.7 \Omega$
- $R_{ON} = R_{OFF} = 1 \Omega$

The peak source and sink current in this case are:

$$I_{\text{source_pk}} = \min\left(10\text{A}, \frac{V_{DD} - V_{EE}}{R_{OH_EFF} + R_{ON} + R_{G_Int}}\right) \approx 5.9\text{A}$$

$$I_{\text{sink_pk}} = \min\left(10\text{A}, \frac{V_{DD} - V_{EE}}{R_{OL} + R_{OFF} + R_{G_Int}}\right) \approx 6.7\text{A} \quad (2)$$

Thus, by using a 1- Ω external gate resistance, the peak source current is 5.9 A, the peak sink current is 6.7 A. The collector-to-emitter dV/dt during the turn on switching transient is dominated by the gate current at the miller plateau voltage. The hybrid pullup structure ensures the peak source current at the miller plateau voltage, unless the turn on gate resistor is too high. The faster the collector-to-emitter, V_{ce} , voltage rises to V_{DC} , the smaller the turn on switching loss is. The dV/dt can be estimated as $Q_g/I_{\text{source_pk}}$. For the turn off switching transient, the drain-to-source dV/dt is dominated by the load current, unless the turn off gate resistor is too high. After V_{ce} reaches the dc bus voltage, the power semiconductor is in saturation mode and the channel current is controlled by V_{ge} . The peak sink current determines the dI/dt , which dominates the V_{ce} voltage overshoot accordingly. If using relatively large turn off gate resistance, the V_{ce} overshoot can be limited. The overshoot can be estimated by:

$$\Delta V_{ce} = L_{\text{stray}} \cdot I_{\text{load}} / ((R_{OFF} + R_{OL} + R_{G_Int}) \cdot C_{ies} \cdot \ln(V_{\text{plat}} / V_{th})) \quad (3)$$

Where

- L_{stray} is the stray inductance in power switching loop, as shown in 图 9-6
- I_{load} is the load current, which is the turn off current of the power semiconductor
- C_{ies} is the input capacitance of the power semiconductor
- V_{plat} is the plateau voltage of the power semiconductor
- V_{th} is the threshold voltage of the power semiconductor

图 9-6. Stray Parasitic Inductance of IGBTs in a Half-Bridge Configuration

The power dissipation must be taken into account to maintain the gate driver within the thermal limit. The power loss of the gate driver includes the quiescent loss and the switching loss, which can be calculated as:

$$P_{DR} = P_Q + P_{SW} \quad (4)$$

P_Q is the quiescent power loss for the driver, which is $I_q \times (VDD - VEE) = 5 \text{ mA} \times 20 \text{ V} = 0.100 \text{ W}$. The quiescent power loss is the power consumed by the internal circuits such as the input stage, reference voltage, logic circuits, protection circuits when the driver is switching when the driver is biased with VDD and VEE, and also the charging and discharging current of the internal circuit when the driver is switching. The power dissipation when the driver is switching can be calculated as:

$$P_{SW} = \frac{1}{2} \cdot \left(\frac{R_{OH_EFF}}{R_{OH_EFF} + R_{ON} + R_{G_Int}} + \frac{R_{OL}}{R_{OL} + R_{OFF} + R_{G_Int}} \right) \cdot (VDD - VEE) \cdot f_{sw} \cdot Q_g \quad (5)$$

Where

- Q_g is the gate charge required at the operation point to fully charge the gate voltage from VEE to VDD
- f_{sw} is the switching frequency

In this example, the P_{SW} can be calculated as:

$$P_{SW} = \frac{1}{2} \cdot \left(\frac{R_{OH_EFF}}{R_{OH_EFF} + R_{ON} + R_{G_Int}} + \frac{R_{OL}}{R_{OL} + R_{OFF} + R_{G_Int}} \right) \cdot (VDD - VEE) \cdot f_{sw} \cdot Q_g = 0.505W \quad (6)$$

Thus, the total power loss is:

$$P_{DR} = P_Q + P_{SW} = 0.10W + 0.505W = 0.605W \quad (7)$$

When the board temperature is 125°C, the junction temperature can be estimated as:

$$T_j = T_b + \psi_{jb} \cdot P_{DR} \approx 150^\circ C \quad (8)$$

Therefore, for the application in this example, with 125°C board temperature, the maximum switching frequency is approximately 50 kHz to keep the gate driver in the thermal limit. By using a lower switching frequency, or increasing external gate resistance, the gate driver can be operated at a higher switching frequency.

9.2.2.6 Overcurrent and Short Circuit Protection

A standard desaturation circuit can be applied to the DESAT pin. If the voltage of the DESAT pin is higher than the threshold V_{DESAT} , the soft turn-off is initiated. A fault is reported to the input side to DSP/MCU. The output is held to LOW after the fault is detected, and can only be reset by the RST/EN pin. The state-of-art overcurrent and short circuit detection time helps to ensure a short shutdown time for SiC MOSFET and IGBT.

If DESAT pin is not in use, it must be tied to COM to avoid overcurrent fault false triggering.

- TI recommends fast reverse recovery high voltage diode in the desaturation circuit. A resistor is recommended in series with the high voltage diode to limit the inrush current.
- TI recommends a Schottky diode from COM to DESAT to prevent driver damage caused by negative voltage.
- TI recommends a Zener diode from COM to DESAT to prevent driver damage caused by positive voltage.

9.2.2.7 Isolated Analog Signal Sensing

The isolated analog signal sensing feature provides a simple isolated channel for the isolated temperature detection, voltage sensing and so forth. One typical application of this function is the temperature monitor of the power semiconductor. Thermal diodes or temperature sensing resistors are integrated in the SiC MOSFET or IGBT module close to the dies to monitor the junction temperature. The UCC21750-Q1 has an internal 200- μ A current source with $\pm 3\%$ accuracy across temperature, which can forward bias the thermal diodes or create a voltage drop on the temperature sensing resistors. The sensed voltage from the AIN pin is passed through the isolation barrier to the input side and transformed to a PWM signal. The duty cycle of the PWM changes linearly from 10% to 88% when the AIN voltage changes from 4.5 V to 0.6 V and can be represented using [方程式 9](#).

$$D_{APWM}(\%) = -20 * V_{AIN} + 100 \quad (9)$$

9.2.2.7.1 Isolated Temperature Sensing

A typical application circuit is shown in [图 9-7](#). To sense temperature, the AIN pin is connected to the thermal diode or thermistor which can be discrete or integrated within the power module. TI recommends a low pass filter for the AIN input. Because the temperature signal does not have a high bandwidth, the low pass filter is mainly used for filtering the noise introduced by the switching of the power device, which does not require stringent control for propagation delay. The filter capacitance for C_{filt} can be chosen between 1 nF to 100 nF and the filter resistance R_{filt} between 1 Ω to 10 Ω according to the noise level.

The output of APWM is directly connected to the microcontroller to measure the duty cycle dependent on the voltage input at AIN, using [方程式 9](#).

图 9-7. Thermal Diode or Thermistor Temperature Sensing Configuration

When a high-precision voltage supply for VCC is used on the primary side of UCC21750-Q1 the duty cycle output of APWM can also be filtered and the voltage measured using the microcontroller's ADC input pin, as shown in 图 9-8. The frequency of APWM is 400 kHz, so the value for R_{filt_2} and C_{filt_2} must be such that the cutoff frequency is below 400 kHz. Temperature does not change rapidly, thus the rise time due to the RC constant of the filter is not under a strict requirement.

图 9-8. APWM Channel with Filtered Output

The example below shows the results using a 4.7-k Ω NTC, NTCS0805E3472FMT, in series with a 3-k Ω resistor and also the thermal diode using four diode-connected MMBT3904 NPN transistors. The sensed voltage of the 4 MMBT3904 thermal diodes connected in series ranges from about 2.5 V to 1.6 V from 25°C to 135°C, corresponding to 50% to 68% duty cycle. The sensed voltage of the NTC thermistor connected in series with the 3-k Ω resistor ranges from about 1.5 V to 0.6 V from 25°C to 135°C, corresponding to 70% to 88% duty cycle. The voltage at VAIN of both sensors and the corresponding measured duty cycle at APWM is shown in 图 9-9.

图 9-9. Thermal Diode and NTC V_{AIN} and Corresponding Duty Cycle at APWM

The duty cycle output has an accuracy of $\pm 3\%$ throughout temperature without any calibration, as shown in 图 9-10 but with single-point calibration at 25°C, the duty accuracy can be improved to $\pm 1\%$, as shown in 图 9-11.

图 9-10. APWM Duty Error Without Calibration

图 9-11. APWM Duty Error With Single-Point Calibration

9.2.2.7.2 Isolated DC Bus Voltage Sensing

The AIN to APWM channel can be used for other applications such as the DC-link voltage sensing, as shown in 图 9-12. The same filtering requirements as given above can be used in this case, as well. The number of attenuation resistors, R_{atten_1} through R_{atten_n} , is dependent on the voltage level and power rating of the resistor. The voltage is finally measured across R_{LV_DC} to monitor the stepped-down voltage of the HV DC-link which must fall within the voltage range of AIN from 0.6 V to 4.5 V. The driver must be referenced to the same point as the measurement reference, thus in the case shown below the UCC21750-Q1 is driving the lower IGBT in the half-bridge and the DC-link voltage measurement is referenced to COM. The internal current source I_{AIN} must be taken into account when designing the resistor divider. The AIN pin voltage is:

$$V_{AIN} = \frac{R_{LV_DC}}{R_{LV_DC} + \sum_{i=1}^n R_{atten_i}} \cdot V_{DC} + R_{LV_DC} \cdot I_{AIN} \quad (10)$$

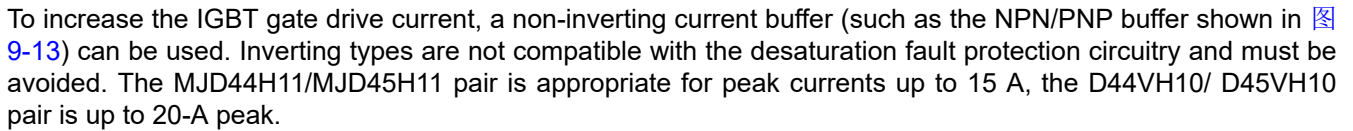

图 9-12. DC-link Voltage Sensing Configuration

9.2.2.8 Higher Output Current Using an External Current Buffer

To increase the IGBT gate drive current, a non-inverting current buffer (such as the NPN/PNP buffer shown in ) can be used. Inverting types are not compatible with the desaturation fault protection circuitry and must be avoided. The MJD44H11/MJD45H11 pair is appropriate for peak currents up to 15 A, the D44VH10/ D45VH10 pair is up to 20-A peak.

In the case of an over-current detection, the soft turn off (STO) is activated. External components must be added to implement STO instead of normal turn off speed when an external buffer is used. C_{STO} sets the timing for soft turn off and R_{STO} limits the inrush current to below the current rating of the internal FET (10A). R_{STO} must be at least $(VDD - VEE)/10$. The soft turn off timing is determined by the internal current source of 400 mA and the capacitor C_{STO} . C_{STO} is calculated using [方程式 11](#).

$$C_{STO} = \frac{I_{STO} \cdot t_{STO}}{VDD - VEE} \tag{11}$$

- I_{STO} is the internal STO current source, 400 mA
- t_{STO} is the desired STO timing

图 9-15. AIN Step Input (Green) and APWM Output (Pink)

10 Power Supply Recommendations

During the turn on and turn off switching transient, the peak source and sink current is provided by the VDD and VEE power supply. The large peak current is possible to drain the VDD and VEE voltage level and cause a voltage droop on the power supplies. To stabilize the power supply and ensure a reliable operation, TI recommends a set of decoupling capacitors at the power supplies. Considering the UCC21750-Q1 has $\pm 10\text{-A}$ peak drive strength and can generate high dV/dt , TI recommends a $10\text{-}\mu\text{F}$ bypass cap between VDD and COM, VEE and COM. TI recommends a $1\text{-}\mu\text{F}$ bypass cap between VCC and GND due to less current comparing with output side power supplies. A $0.1\text{-}\mu\text{F}$ decoupling cap is also recommended for each power supply to filter out high frequency noise. The decoupling capacitors must be low ESR and ESL to avoid high frequency noise, and must be placed as close as possible to the VCC, VDD and VEE pins to prevent noise coupling from the system parasitics of PCB layout.

11 Layout

11.1 Layout Guidelines

Due to the strong drive strength of the UCC21750-Q1, careful considerations must be taken in PCB design. Below are some key points:

- The driver must be placed as close as possible to the power semiconductor to reduce the parasitic inductance of the gate loop on the PCB traces.
- The decoupling capacitors of the input and output power supplies must be placed as close as possible to the power supply pins. The peak current generated at each switching transient can cause high di/dt and voltage spike on the parasitic inductance of PCB traces.
- The driver COM pin must be connected to the Kelvin connection of SiC MOSFET source or IGBT emitter. If the power device does not have a split Kelvin source or emitter, the COM pin must be connected as close as possible to the source or emitter terminal of the power device package to separate the gate loop from the high power switching loop
- Use a ground plane on the input side to shield the input signals. The input signals can be distorted by the high frequency noise generated by the output side switching transients. The ground plane provides a low-inductance filter for the return current flow.
- If the gate driver is used for the low side switch which the COM pin connected to the dc bus negative, use the ground plane on the output side to shield the output signals from the noise generated by the switch node; if the gate driver is used for the high side switch, which the COM pin is connected to the switch node, ground plane is not recommended
- If ground plane is not used on the output side, separate the return path of the DESAT and AIN ground loop from the gate loop ground which has large peak source and sink current.
- No PCB trace or copper is allowed under the gate driver. TI recommends a PCB cutout to avoid any noise coupling between the input and output side which can contaminate the isolation barrier.

(1) **Status:** For more details on status, see our [product life cycle](#).

(2) **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

(4) **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

(5) **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.
